Abstract

By employing 1995-2000 data on European regions we construct an index of regional openness based on the share of hotels on population and the share of population that speaks a second language. This index has an impact on regional performance after controlling for technological capabilities, agglomeration economies, and other factors. Apart from a direct effect of openness, we find an indirect effect coming through patents. This suggests that open regions tap into wider knowledge networks that then affect performance. From a policy perspective, making a region less “provincial” can be as important as investments in local infrastructures and networks.

Keywords: openness, regional performance, regional advantages, technology, European regions.

9 Nous appuyant sur des données sur les régions européennes pour la période 1995-2000, nous établissons
10 un indice d'ouverture régionale basé sur la proportion d'hôtels par rapport à la population et sur la
11 proportion de la population qui parle une deuxième langue. Cet indice a un impact sur les performances
12 régionales d'après le contrôle des capacités technologiques, des économies d'agglomération et d'autres
13 facteurs. Outre un effet d'ouverture direct, nous observons un effet indirect causé par les brevets. Cela
14 laisse à penser que les régions ouvertes puisent dans des réseaux de connaissances beaucoup plus larges,
15 ce qui entraîne un effet sur les performances. Dans une perspective politique, il peut être aussi important
16 de rendre une région moins provinciale que d'investir dans des infrastructures et des réseaux locaux.

34 **Wie 'provinziell' ist Ihre Region? Offenheit und regionale Leistung in Europa**

35 Alfonso Gambardella, Myriam Mariani and Salvatore Torrìsi
36

37 Unter Nutzung von Daten über europäische Regionen im Zeitraum von 1995 bis 2000
38 konstruieren wir einen Index der regionalen Offenheit anhand des Anteils von Hotels an der
39 Bevölkerung sowie des Anteils der Bevölkerung mit Fremdsprachenkenntnissen. Dieser Index
40 wirkt sich auf die regionale Leistung aus, wenn man auf technologische Fähigkeiten,
41 Agglomerationswirtschaften und weitere Faktoren kontrolliert. Abgesehen von einer direkten
42 Auswirkung der Offenheit stellen wir eine indirekte Auswirkung durch Patente fest. Dies weist
43 darauf hin, dass sich offene Regionen breitere Wissensnetzwerke zunutze machen, welche sich
44 ihrerseits auf die Leistung auswirken. Von der politischen Warte aus betrachtet kann es
45 genauso wichtig sein, eine Region weniger 'provinziell' zu machen, wie es wichtig ist, in lokale
46 Infrastrukturen und Netzwerke zu investieren.

20
21 Empleado datos de 1995-2000 sobre las regiones europeas, construimos un índice de
22 accesibilidad regional basado en la proporción de hoteles en la población y la proporción de la
23 población que habla una segunda lengua. Este índice tiene un efecto en el desempeño regional
24 si se controlan las capacidades tecnológicas, las economías de aglomeración y otros factores.
25 Aparte de un efecto directo de accesibilidad, observamos un efecto indirecto que procede de
26 las patentes. Esto sugiere que las regiones abiertas aprovechan redes más amplias de
27 conocimiento que luego afectan al desempeño. Desde una perspectiva política, puede ser tan
28 importante conseguir que una región sea menos "provincial" como invertir en infraestructuras y
29 redes locales.

1. INTRODUCTION

Regional performance has drawn increasing attention in recent years. Its growing popularity owes a great deal to the fortunes of some regions of the world. For example, the story of Silicon Valley prompted Saxenian (1994) to dig into the determinants of “regional advantages.” At the same time, regional inequalities have raised a good deal of attention, especially in Europe (CEC, 2007).

A classical explanation of regional advantages is local infrastructures and the local milieu for innovation and growth (e.g., Porter, 1998; Swann *et al.*, 1998; Döring and Schnellenbach, 2006). Another explanation is technology. Audretsch and Feldman (1996) showed that in the US technological activities tend to cluster. Verspagen (1997) and Caniels (1999) obtained similar results for Europe. Fagerberg *et al* (1997) found that the R&D-intensity of European regions positively affects their GDP growth, while Paci and Usai (2000) found that in Europe regional patents per capita are positively correlated with labor productivity.

The goal of this paper is to show that another determinant of regional advantages is their “openness,” and particularly their international openness. We study empirically the extent to which openness contributes to the economic performance of the European regions. While there is an established literature on openness at the level of countries, there is not much at the regional level. This is a serious gap because there are differences across regions within a country. Apart from performance, they exhibit differences in industrial or technological activity, as well as in their attitude towards openness.

Moreover, the present literature on countries has focused on the classical trade-openness (export plus imports as a share of GDP). But in a world in which knowledge, services, along with intangible skills, assets, or linkages have become more important, there are subtle elements of openness that are not fully captured by these classical

1 measures. We then broaden the concept of openness from mere trade-openness to the
2
3 ability of regions to capture external opportunities. This ability depends on the extent to
4
5 which the region is connected to the external world, which in turn depends on factors
6
7 such as the inward or outward mobility of people (e.g., students, human capital,
8
9 workers), the presence of multinational enterprises, the familiarity of the local
10
11 population with international languages or with other cultures.
12
13

14
15 Clearly, these factors also affect trade, as they may result in greater exports or
16
17 imports. Yet, this is not key for us. What we are interested in is the extent to which a
18
19 region is embedded in broad networks. This affects its productivity in several ways.
20
21 Apart from greater exports or imports, or classical advantages from trade specialization,
22
23 a region that is hooked into wider networks benefits earlier or more effectively from
24
25 international knowledge spillovers or from other growth opportunities (e.g., shocks to
26
27 international demand). Similarly, these networks provide exposure to knowledge,
28
29 resources, learning processes, or to more advanced benchmarks or best-practices that
30
31 enable the regions to produce better or more advanced goods and services, or to make
32
33 more productive investments. In light of the greater importance of intangible goods,
34
35 services, and knowledge in economic activities, all these factors – and the associated
36
37 “soft” linkages – have become increasingly important for economic performance. Many
38
39 fast-growing regions of the world today – e.g., Taiwan, Singapore, South Korea,
40
41 Ireland, Israel, or the software industry in Bangalore or other Indian regions – have
42
43 based their growth on patterns of international openness like the ones that we are
44
45 highlighting here. Apart from exports and imports, their international connections with
46
47 leading countries through knowledge channels, mobility of people, multinational firms,
48
49 familiarity with the English language, have been crucial for their success (e.g.,
50
51 Bresnahan and Gambardella, 2004; Arora and Gambardella, 2005).
52
53
54
55
56
57
58
59
60

1 We employ data on European NUTS (Nomenclature des Unités Territoriales
2 Statistiques) regions from the Eurostat database REGIO. To measure regional
3 performance we use a proxy of regional labor productivity. We divide our data into two
4 periods: 1995-1997 and 1998-2000. Since openness changes slowly, yearly data may be
5 too short a window, and they could boost the statistical significance of our results
6 simply because they repeat observations over time. We then average out yearly
7 variables over the three years.
8
9

10 Along with controls, we regress our measure of regional performance on measures
11 of technological competencies, agglomeration, and openness. We measure technological
12 competencies by the stock of patents in the region, and agglomeration factors by
13 population density. Both are standard measures of these variables (e.g., Ciccone, 2002).
14 To measure openness we have to deal with two issues. First, as noted, standard
15 measures of trade-openness are not available at the regional level. Second, we seek
16 measures that capture the ability of a region to communicate and interact outside its
17 boundaries and to be part of international networks or learning processes, rather than
18 just classical trade measures. We then construct an index of openness composed of an
19 estimate of the regional population share who speaks a foreign language and the share
20 of hotels on the population of the region.
21

33
34
35
36
37
38
39
40
41
42

43 After controlling for endogeneity we find that technological competencies,
44 agglomeration, and openness have positive impacts on the performance of regions. In
45 addition, we find that openness has an indirect effect on performance through
46 technology, viz. openness boosts scientific and technological activities, which in turn
47 affect regional economic performance.

60

1 equation. Section 4 presents our analysis and results of the two-equation model with the
2
3
4 estimated direct and indirect effects of openness. Section 5 concludes.
5
6
7

8 **2. BENEFITS OF OPENNESS**

9

10 The existing literature on economic openness has focused on the openness of countries.
11
12 To our knowledge, this paper is one of the few studies that looks at the openness of
13
14 regions within countries.¹ There are advantages in moving from the country to the
15
16 regional level. In particular, the analysis of openness at the country-level neglects the
17
18 considerable differences in both the openness and the economic performance of regions
19
20 within countries. This is especially true for Europe. In the 1990s about one-fourth of the
21
22 population of the European Union (EU) lived in regions whose per-capita income was
23
24 lower than 75% of the EU average. In the US, only Mississippi and West Virginia,
25
26 which cover 2% of the US population, have a per-capita income lower than 75% of the
27
28 US average (Puga, 1999).
29
30
31
32
33

34 At the regional level there are neither systematic data on international exports and
35
36 imports, nor on inward and outward flows of goods and services to other regions within
37
38 the same country. Moreover, there are no data on other variables typically used by the
39
40 international literature, like foreign direct investments. However, as noted, the scope of
41
42 this paper is to examine the impact of a broader concept of openness. The proxies of
43
44 openness that we use in our empirical analysis – viz. the familiarity with a foreign
45
46 language, and the receptivity of the regions to non-resident visitors – are correlated with
47
48 some basic factors associated with the openness of regions, which includes trade-
49
50 openness itself. But they are more primitive than trade-openness in the sense that they
51
52 can cause trade flows along with other opportunities. Ultimately, this means that the
53
54 only relevant limitation due to the lack of data on trade flows at the regional level is that
55
56 we cannot estimate their effects separately from knowledge spillovers, linkages, or other
57
58
59
60

1 flows of information.
2

3 Within the literature on openness at the level of countries, Frankel and Romer
4 (1999) is a key reference. They study the effects of trade (exports plus imports over
5 GDP) as a measure of openness on income per capita for a sample of countries
6 worldwide, and find a positive relationship. Two features of their study are similar to
7 the ones that we propose in this paper. First, unlike previous studies, they use
8 instrumental variables to control for the endogeneity of trade. Second, they recognize
9 that their measure of trade-openness may be a proxy for the many ways in which
10 interactions between countries affect income – e.g., specialization, increasing returns
11 associated with larger markets, mobility of people, and wider knowledge spillovers. In
12 this respect, they also take the approach, as we do in this paper, that the advantages and
13 sources of openness are broader than the mere export-import phenomenon. Alcalà and
14 Ciccone (2004) is another relevant study in this context. Their approach is similar to
15 Frankel and Romer. They find similar results at the country level after instrumenting for
16 both trade-openness and the institutional quality of countries.
17

18 The perception that there are some basic factors that reduce trade costs, raise the
19 openness of a country, and through that affect income in various ways, has become
20 widely accepted. One factor that has drawn increasing attention is the knowledge of the
21 English language. In 2001 the European Edition of *Business Week* (2001) argued that in
22 European business there is an increasing divide between those who know English and
23 those who do not. The article reports that in Continental Europe only 41% of people
24 speak English, and only 29% speak it well enough to carry on a conversation. It also
25 reports that, in several jobs, from factory floors to offices, workers who speak English
26 command 25% to 35% higher salaries.
27

28 A good example of the set of factors that may reduce the cost of international
29 openness, and give rise to corresponding benefits in terms of growth and incomes, is
30

1 provided by Arora *et al.* (2004). In the 1990s the international demand for information
2 technology (IT) services boomed in the developed countries, and particularly in the US.
3
4
5
6 This has produced an IT skill shortage in these countries, to which IT producing and
7
8
9 using firms have responded by outsourcing some of their activities to new locations.
10
11 Several emerging economies were in the position to offer their services, but only a few
12
13 have been able to catch the new market opportunities, particularly India, Ireland, and
14
15 Israel. A critical reason was their natural exposure to international linkages in the form
16
17 of language and connections with skilled emigrants, along with access to the services of
18
19 foreign institutions such as multinational corporations and venture capital firms.
20
21

22
23 Unfortunately, we do not have systematic data on the movement of immigrants
24
25 from and to the regions. However, our goal is to highlight more generally the benefits to
26
27 an individual country or region produced by “soft” linkages with the international
28
29 setting, like flows of knowledge, expertise, and communication. The cases of Indian,
30
31 Irish, or Israeli immigrants in recent years exemplify these processes as these
32
33 immigrants have, among other types of linkages, several knowledge and information
34
35 ties with their countries of origin, and these flows of knowledge or information have
36
37 shown to be important elements of their success since the 1990s.
38
39
40

41
42 The same can be said about multinational firms or relationships to international
43
44 sources of capital. We lack systematic data on the presence of multinational firms or
45
46 access to international capital at the regional level. Yet openness to multinationals or
47
48 international capital enhance the opportunities of a region to take advantage of shocks
49
50 that increase the ability of regional economies to benefit from knowledge by more
51
52 advanced organizations, institutions, or markets. For example, many Irish software
53
54 firms have benefited from spillovers associated with the presence of multinational firms
55
56 in Ireland, mostly in the form of job mobility. As an illustration, DLG, a small Irish firm
57
58 specialized in localization software development and testing (62 employees), has greatly
59
60

1 benefited from its managing director's previous working experience with Lotus, which
2 helped consolidate links between the two firms. The director has helped the DLG staff
3 to absorb organizational and management best practices from Lotus. Moreover, many
4 successful Irish software firms have started as programming houses (subcontractors) for
5 the local subsidiaries of multinational corporations and have then exploited the network
6 and reputation of these customers to gain access to foreign markets.
7
8
9
10
11
12
13
14

15 To summarize, the discussion in this Section suggests that openness per se, which
16 includes participation in international knowledge flows, links to international networks,
17 ability to capture opportunities that arise at the international level, or openness to the
18 presence of multinational enterprises, can have important implications for the economic
19 performance of a region. These implications can take the form of sources of demand,
20 spillovers, or transfers of best practices, which go beyond the mere trade flows.

22
23
24
25
26
27
28
29
30
31

32 **3. REGIONAL PERFORMANCE IN EUROPE**

33 **3.1 Sample, data, variables, and their sources**

34 Our empirical analysis is based on a sample of NUTS European regions. The source of
35 data is the Eurostat REGIO data base (2004 edition). We employed NUTS2 regions for
36 Austria, Belgium, Finland, Germany, Greece, Ireland, Italy, the Netherlands, Portugal,
37 Spain, and Sweden (e.g., Oberbayern, Niederbayern, Lombardy, Cataluña). For France
38 and the UK we were forced to use NUTS1 regions (e.g., Eastern Regions instead of East
39 Anglia or Essex) because of too many missing values for their NUTS2 regions. For the
40 same reason we could only use data for Denmark as a whole. These cases, however, are
41 unlikely to create any particular problem in our analysis, since we control for area and
42 population of regions.
43
44
45
46
47
48
49
50
51
52
53
54
55
56

57 The dependent variable and all the covariates that we are interested in are
58 available for 1995-2000. However, rather than using an annual panel of regions and
59
60

1 years we divided our time dimension into two periods, 1995-1997 and 1998-2000, and
2
3 we averaged out our variables over each three year period. As noted in the Introduction,
4
5 yearly data may represent too short intervals. Changes in openness, technological
6
7 capabilities, or population density occur in longer time spans. The use of annual data
8
9 would be like running monthly data for classical annual panel estimation. This would
10
11 boost the statistical significance of the regressors because of repeated observations of
12
13 the dependent variable for each covariate. Thus, as a conservative approach we lumped
14
15 the six year period in two three year periods.
16
17
18
19

20 The number of observations in our sample varies from 248 to 164 because of
21
22 differences in missing data for our instruments. Since we use time and country
23
24 dummies, and there are no reasons to believe that the missing data are systematic, we
25
26 run our regressions with all the available information for that regression. However, the
27
28 empirical results of this paper do not change considerably when we run our regressions
29
30 on the sample common to all the specifications. Also, in spite of the missing data, the
31
32 number of observations in each of the two sample periods, 1995-1997 and 1998-2000, is
33
34 fairly balanced. Our dependent variable is the region GDP over the population ages
35
36 between 25-65. We interpret it as a proxy for region labor productivity.²
37
38
39
40

41 Table 1 lists and defines the variables employed in our analysis. Table 2 reports
42
43 descriptive statistics. We employed databases other than REGIO for UNILAB95,
44
45 LANG, and LANG18. To obtain UNILAB95 we downloaded information on about
46
47 21,000 research laboratories located in Europe from the *European R&D database 1996*
48
49 produced by Reed Elsevier Publisher. Of these, 5,271 were university laboratories for
50
51 which we recorded address and zip-code in order to assign each laboratory to the region
52
53 in which it was located. The variables LANG and LANG18 were obtained from the
54
55 *Special Survey on Languages* performed in 2000 by Eurobarometer (European Opinion
56
57 Research Group). This survey interviewed nearly 16,000 people in 15 European
58
59
60

1 countries, and it provided the NUTS region of the interviewees. We computed the
 2 shares of individuals over 27 years of age in each region who speak at least one foreign
 3 language, and the share of individuals who learned it before they were 18. As we shall
 4 see, we use LANG18 as an instrument for LANG. The 27-year-old threshold enables us
 5 to construct this instrument, which we could not create if we took the share of the entire
 6 population, and to focus on individuals of working age. Since the share of individuals
 7 over 27 is computed at the beginning of our two time periods, LANG and LANG18
 8 vary over time as well.³

TABLE 1 AND 2 ABOUT HERE

3.2 Regional Performance: Specification

We start by estimating the following log-linear equation:

$$\begin{aligned} \log(Y_{it}) = & \text{constant} + \text{country dummies} + \text{time dummy} + \\ & \alpha_{OPEN} \cdot [\alpha_{HOTEL} \cdot \log(HOTEL_{it}) + (1 - \alpha_{HOTEL}) \cdot \log(LANG_{it})] + \\ & \alpha_{TECH} \cdot \log(TECH_{it}) + \alpha_{DENS} \cdot \log(DENS_{it}) + \\ & \alpha_{POP} \cdot \log(POP_{it}) + \text{controls} + \varepsilon_{it} \end{aligned} \quad (1)$$

where the α are parameters to be estimated, ε_{it} is the error-term, TECH is alternatively HRSTE or KPAT, and all the other variables are defined in Table 1.

The term in the square bracket is our index of openness. We measure openness as a combination of two factors: the share of hotels on population (HOTEL) and our language measure (LANG), which proxies for the share of the regional population that speaks a foreign language. The parameter α_{HOTEL} estimates the weight of HOTEL vs. LANG, while α_{OPEN} measures the impact of openness on regional performance.

The variable LANG is clearly correlated with the extent to which a region is linked to, communicates with, or can reach outside of its boundaries. Our discussion in

1 Section 2 suggests that we may want to use the knowledge of English rather than
2 generically of a second language. Since the Eurobarometer survey reports the specific
3 languages known by the surveyed individuals, we constructed the English analog of
4 LANG, i.e., the share of the population that speaks English. However, the reason why
5 we employ LANG is because knowing English is not the right measure for British
6 regions. At any rate, in Section 4.2 we present as a robustness check our regressions
7 with the English equivalent of LANG and after removing the British regions from our
8 sample. All our empirical results do not change.

9
10 We think that HOTEL, which accounts for the capability of a region to host non-
11 residents, provides a natural complement to LANG as a measure of openness in our
12 framework. The variable LANG accounts for many of the factors that we discussed in
13 Section 2. Clearly, knowledge of languages is a specific measure of the ability to
14 communicate internationally, and in this respect it is a proxy for the extent to which the
15 people in a region interact with the environment outside the region itself. This is partly
16 captured by HOTEL as well, as a region with a larger number of hotels is more open to
17 the inward and outward movement of people. To some extent, we may suggest that
18 while LANG is more likely to be a measure of the soft international linkages widely
19 discussed in Section 2, HOTEL may account to a greater extent for more traditional
20 openness, like the flow of businessmen to the region. However, rather than going
21 further in this distinction, the use of more proxies for openness spans more dimensions
22 of the latent variable that we intend to measure.

23
24 The REGIO dataset provides other potential measures of openness like the
25 number of airplane passengers or the annual number of non-residents spending nights in
26 hotels or other accommodations (e.g., camping), which we tried as additional
27 components of our index. However, they are correlated with HOTEL and LANG, add
28 no statistical power to our estimation, and produce collinearity. Moreover, not only is an

1 index using only a few indicators justified *empirically* by this correlation, but also
2
3 *theoretically*, because most of the factors that account for the openness of a location are
4
5 themselves correlated with each other. For example, the Asian Tigers, Ireland, Israel, or
6
7 the Indian software industry show high levels of exports; they benefit from international
8
9 spillovers because of their international linkages (i.e., emigrants, the use of the English
10
11 language, etc.); they are open to multinational enterprises; they are part of an extensive
12
13 division of labor particularly with the US (Arora *et al.* 2004). In sum, given our limited
14
15 number of observations, HOTEL and LANG cover the most parsimonious set of proxies
16
17 for our purposes.
18
19
20
21

22 A potential concern is that HOTEL and LANG may capture the effect of tourism
23 on regional performance. However, at the level of NUTS1 and NUTS2 regions, tourism
24 covers a small share of regional economic activities. A report of the Italian Ministry of
25 Industry on the economic perspectives of tourism in Italy indicates that direct and
26 indirect activities linked to the tourist sector account for 5% of the Italian GDP, and for
27 8% of the GDP of the most tourist NUTS2 regions (*Ministero dell'Industria*, 2000).
28 Since these figures include activities that are very indirectly associated with tourism
29 (e.g., the food industry), the effective share of relevant tourist activities can be quite
30 smaller and their direct effect on regional GDP is largely negligible. At any rate, as
31 listed in Table 1, we include a control for the tourist intensity of the region in our
32 regressions, TOURISM. This is the share of annual arrivals of non-residents in the
33 region who are accommodated in establishments other than hotels, e.g., camping or
34 hostels, which is clearly associated with tourist activities.
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51
52

53 Finally, both HOTEL and LANG are long-run variables. One reason for
54 preferring HOTEL to other measures provided by REGIO, like the non-residents
55 spending nights in the region or the number of beds available, is that these variables are
56 more likely to be affected by short-term factors, whereas building new hotels has a
57
58
59
60

1 longer gestation. Similarly, since learning a language takes months or years, the share of
2 population that knows a second language is unlikely to be fickle in the short-run. As we
3 shall see below, we also instrument for LANG, and then in a subsequent specification
4 for HOTEL, to eliminate further potential endogeneity.
5
6
7
8
9

10 As far as the other covariates are concerned, we employ HRSTE or KPAT as
11 measures of regional skills or technological capabilities. The former is broader than just
12 patents. However, since the 1990s there has been a significant upsurge in patenting, and
13 patent stocks increasingly reflect relevant technological outputs. Moreover, unlike
14 HRSTE, which is an input, patents account for actual technological achievements. At
15 the same time, HRSTE may be affected by differences in the employment levels of
16 educated individuals across regions. By alternating the two measures we can check for
17 potentially different effects. We also include them jointly, but their collinearity reduces
18 their significance.
19
20
21
22
23
24
25
26
27
28
29
30

31 We tried several variables as controls. We employed the share of agricultural or
32 arable land, or whether the region borders with the sea. We also introduced a covariate
33 accounting for the level of capital formation in the region. Unfortunately, there are
34 many missing observations for this variable in REGIO. We therefore used it along with
35 a dummy for missing observations, and to avoid endogeneity we lagged it by three
36 periods. In general, the effect of capital formation and that of the other controls were
37 statistically not significant, and all the results presented below are robust to these
38 different specifications. Only the length of motorways in the regions (MTW_{it}) was
39 statistically significant in some specifications. To be parsimonious with the regressors,
40 and in light of the correlation among the many potential controls, we decided to use
41 MTW_{it} as our summary control for the characteristics of regions not accounted for by the
42 other covariates. As noted earlier, we also included a control for the tourist intensity of
43 the region.
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1 We estimated (1) by OLS and then by gradually instrumenting different
2
3 potentially endogenous covariates. We first instrumented for LANG and our technology
4
5 variables, HRSTE or KPAT, by using LANG18 and UNILABS95. They are the two
6
7 covariates in our regressions that would most likely suffer from endogeneity.
8
9

10 Knowledge of a second language could be the outcome of a richer region because
11
12 higher income per capita may induce greater openness and related investments. This is
13
14 pretty much the reason why the literature on openness at the level of countries, and
15
16 particularly Frankel and Romer (1999), instrumented for their measures of trade-
17
18 openness. Our instrument, LANG18, ignores individuals who might have learned the
19
20 language because of recent shocks. Our 27-year-old threshold then ensures at least a 10
21
22 year window between the current knowledge of the language and the period in which it
23
24 was learned. This makes it more likely that our language measure is a cause and not a
25
26 consequence of regional performance. The need for instrumenting for HOTEL is less
27
28 compelling. As with any kind of construction, hotels typically require time to be built.
29
30 Hence, they could be taken as fixed in the short-run.
31
32
33
34
35

36 It is more important to instrument for the technological development of the
37
38 region. Both HRSTE and KPAT are stock measures, and hence they can also be taken
39
40 as exogenous in the short-run. Yet in the period that we are considering, economic
41
42 development, especially in an advanced setting like Europe, had already become
43
44 increasingly dependent on technology and innovation. Therefore, we need to take into
45
46 account whether HRSTE or KPAT cause such processes, or if they are affected by
47
48 shocks that also affect per-capita income. The stock of university labs in 1995,
49
50 UNILABS95, is a more exogenous measure of the scientific and technological
51
52 capabilities of the region because it is fully pre-sample. Moreover, university labs take
53
54 time to be established and hence they reflect a long history of scientific or technological
55
56 skills in the area. Also, since UNILABS95 only accounts for university labs, this
57
58
59
60

1 measures an even more indirect contribution to regional performance than if we
 2 included industry labs as well.
 3
 4

5
 6 Finally, we report a specification in which we employed lagged or pre-sample
 7 variables as instruments for all the covariates in (1) apart from the constant, the
 8 dummies, AREA, and TOURISM. Specifically, we employed the following instruments
 9 (see Table 1 for definitions): *constant*, *country dummies*, *time dummy*, $\log(\text{POP}_{it-2})$,
 10 $\log(\text{AREA}_i)$, $\log(\text{MTW}_{it-2})$, $\log(\text{UNILAB95}_i)$, $\log(\text{PASS}_{it-4})$, $\log(\text{LANG18}_{it})$. Population
 11 and motorways are lagged two periods because REGIO contained many missing values
 12 for these variables before 1989. However, the two-period lag implies that both variables
 13 are fully pre-sample. Note that it is important to instrument for population in our
 14 analysis, as current population also appears as the denominator of the dependent
 15 variable. Unfortunately, we could not use a lagged instrument for HOTEL because
 16 REGIO only reports this variable since 1995. We then looked for a pre-sample measure
 17 that could be correlated with it. REGIO provides a long-time series on airplane
 18 passengers embarked and disembarked in the region, which is clearly correlated with
 19 the number of people visiting the region, and hence with HOTEL. Since PASS may also
 20 be a consequence rather than a cause of regional performance we deliberately picked the
 21 longest possible lag that we could construct, which was four periods.

46 **3.3 Regional Performance: Empirical Results**

47 Table 3 reports our OLS and two IV regressions, which we label IV(1) and IV(2). In the
 48 first three columns we employ HRSTE as a measure of technological capabilities, while
 49 in the final three columns we employ KPAT.
 50
 51
 52
 53
 54

55 TABLE 3 ABOUT HERE

56 We performed a Wu-Hausman specification test to assess whether the key
 57 parameters of our analysis, i.e., α_{OPEN} , α_{HOTEL} , and α_{HRSTE} or α_{KPAT} , were jointly
 58
 59
 60

1 different in IV(1) with respect to OLS, and in IV(2) with respect to IV(1). The test
2
3
4 computes the statistic $(\alpha_1 - \alpha_0)'(\mathbf{V}_1 - \mathbf{V}_0)^{-1}(\alpha_1 - \alpha_0)$ where $\alpha_1 - \alpha_0$ is the difference
5
6 between the estimated parameter vectors under the tested and the efficient specification,
7
8 i.e., IV(1) and OLS or IV(2) and IV(1) in our case, and $\mathbf{V}_1 - \mathbf{V}_0$ is the difference in the
9
10 variance-covariance matrices of α_1 and α_0 . This statistic is distributed as χ^2 with
11
12 degrees of freedom equal to the number of tested parameters. In the HRSTE
13
14 specification, the test statistic was 6.46 in the IV(1) vs. the OLS test, which implies
15
16 rejection of the null hypothesis of equality of the coefficients at $p < 10\%$, and 36.30 in
17
18 the IV(2) vs. the IV(1) test, which rejects the null hypothesis at $p < 1\%$. In the KPAT
19
20 specifications the two statistics were respectively 2.14, which does not reject the null
21
22 hypothesis in IV(1) vs. OLS, and 37.67, which rejects the null hypothesis in IV(2) vs.
23
24 IV(1) at $p < 1\%$.

25
26
27
28
29
30 Our estimated elasticity of openness, α_{OPEN} , is around 0.25 in the HRSTE-
31
32 regressions, and it drops by about half in the KPAT-regressions. In the HRSTE-
33
34 regressions α_{OPEN} is significant at $p < 1\%$ or $p < 5\%$. Similarly, in the KPAT-
35
36 regressions it is significant at $p < 1\%$ in OLS and IV(1), while its p-value is barely
37
38 higher than 10% in IV(2). The lower significance of α_{OPEN} in the latter case is not a
39
40 major concern. The drop in statistical significance is fairly natural given that we use
41
42 instrumental variables and we do not have a very high number of observations.
43
44 Moreover, when we tested for the significance of $\alpha_{OPEN} * \alpha_{HOTEL}$ in the IV(2) equation
45
46 with KPAT, the corresponding p-value was 6.3%, well below 10%. Finally, in the
47
48 HRSTE-equations the estimated weight α_{HOTEL} indicates that about three-fourths of the
49
50 openness index is accounted for by HOTEL and one-fourth by LANG, while in the
51
52 KPAT-equations the weight of HOTEL increases to basically 1 in the IV(2) equation.
53
54 Finally, the estimated effects of our index of openness are not small. To provide a sense
55
56
57
58
59
60

1 of the orders of magnitude involved, we look at a one standard deviation change in
 2 HOTEL centered around the sample average of this variable, when all else is held
 3 constant. From Table 2 this relative change is $\frac{\Delta HOTEL}{HOTEL} = \frac{1.049}{0.659} = 1.592$. Given the
 4
 5
 6
 7
 8
 9
 10 estimated parameters of IV(2) with KPAT in Table 3, the corresponding relative
 11
 12 increase in income $\frac{\Delta Y}{Y}$ is $0.151 * 0.997 * 1.592 = 0.240$, i.e. about one-fourth of the
 13
 14
 15
 16 relative change in HOTEL. Note from Table 2 that a one standard deviation increase in
 17
 18 income centered around its sample mean is $9.954/36.641 = 0.272$. The relative one
 19
 20 standard deviation change in HOTEL then produces an estimated relative change in
 21
 22 income (0.240) slightly smaller than the equivalent relative one standard deviation
 23
 24
 25 increase in income in our sample (0.272).
 26

27
 28 Our estimated elasticities of openness are smaller than both Frankel and Romer
 29
 30 (1999) and Alcalà and Ciccone (2004). Frankel and Romer's IV elasticity of trade-
 31
 32 openness is about 2, while in Alcalà and Ciccone it is slightly higher than 1. An obvious
 33
 34 reason for this difference is that they measure the impact of trade-openness while we
 35
 36 use a different measure of openness. Moreover, we look at the impact of openness on
 37
 38 regional performance as opposed to countries. Thus, comparing the magnitudes of the
 39
 40 impacts of openness between our study and the country studies is not meaningful. More
 41
 42 important is the fact that, in spite of our different settings (regions vs. countries),
 43
 44 samples (European regions vs. countries worldwide), and measures of openness (trade
 45
 46 vs. a broader measure of openness), we also find a positive and significant impact of
 47
 48 openness on performance after controlling for its endogeneity.
 49
 50
 51
 52

53
 54 We confirm previous results in the literature on the impact of technology and
 55
 56 agglomeration on regional performance. First, HRSTE has a sizable and significant
 57
 58 impact, and so does KPAT in the second set of equations. This is consistent with
 59
 60

1 previous work on the role of research, technology and innovation in producing
2 differences across European regions. Among the others, our finding mirrors the results
3 by Fagerberg *et al.* (1997) and Paci and Usai (2000) on the positive relation between
4 R&D or technological capabilities and regional performance in Europe. Second, we find
5 that population density also has a positive and significant impact on regional
6 performance. Thus, our results confirm the two classical explanations of regional
7 advantage – technology and agglomeration economies. Our contribution is that
8 openness also matters, even after controlling for technology and agglomeration.
9

10 The negative and significant effect of population accounts for diminishing returns.
11 The variable MTW does not seem to have an important effect. The effect of motorway
12 infrastructures is probably captured by some of the other covariates. The impact of
13 TOURISM is negative and fairly well measured. As discussed earlier, this variable was
14 included to control for the possibility that our measure of openness captures the impact
15 of the tourist intensity of the region. Since tourist regions are typically also less wealthy,
16 the negative sign of TOURISM was expected. As noted earlier, we also tried other
17 variables in the regressions and none of them were statistically significant.
18
19

20 **4. DIRECT AND INDIRECT EFFECTS OF OPENNESS**

21 **4.1 Specification and results**

22 The drop in the elasticity of openness when we use KPAT instead of HRSTE suggests
23 that KPAT captures part of the effects of openness. Patents are a measure of output, and
24 therefore they are functions of technological inputs like HRSTE or openness. Since
25 knowledge is fertilized by other knowledge and ideas, openness may contribute to
26 innovation output by providing access to a wider set of knowledge sources. Thus,
27 openness may have a direct effect on productivity and an indirect one through patents.
28
29

30 To test for the presence of these effects, we jointly estimate two equations. The
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1 first one is our equation for regional performance (1) with KPAT as the TECH
 2 regressor. The second equation explains KPAT as a function of the same covariates in
 3
 4
 5
 6 (1) with HRSTE in lieu of TECH, viz.

$$\begin{aligned}
 \log(KPAT_{it}) = & \text{constant} + \text{country dummies} + \text{time dummy} + \\
 & \beta_{OPEN} \cdot [\beta_{HOTEL} \cdot \log(HOTEL_{it}) + (1 - \beta_{HOTEL}) \cdot \log(LANG_{it})] + \\
 & \beta_{TECH} \cdot \log(HRSTE_{it}) + \beta_{DENS} \cdot \log(DENS_{it}) + \\
 & \beta_{POP} \cdot \log(POP_{it}) + \text{controls} + \mu_{it} \qquad (2)
 \end{aligned}$$

17 where the β are parameters to be estimated, μ_{it} is the error-term, and HRSTE is an input
 18 for the production of patents. In this two-equation estimation we employ the same
 19
 20
 21
 22
 23 instruments used in our single-equation estimation.⁴

24
 25
 26 Note that in (2) we allow for a different index of openness than in the regional
 27 performance equation, as we let the weights be different than in (1). In principle, if the
 28 expression in the square brackets is a measure of openness it should be the same in both
 29
 30
 31
 32
 33 equations as it represents the same type of variable. In this case, β_{OPEN} and α_{OPEN} in

From a purely empirical point of view, different weights imply a more general
 specification. At the same time, since our index of openness is a proxy for an underlying
 concept, a more flexible specification can capture potentially different components of
 this covariate. For the same reason, different components of our index may have
 different importance in different specifications, and we can assess which aspect of
 openness affects regional performance vs. regional technological capabilities.

The results of our joint estimation of (1) and (2) are in Table 4. The estimated
 parameters in the regional performance equation are similar to those in Table 3. In
 addition, our index of openness has a sizable and significant impact on KPAT. This

1 confirms that openness has both a direct and an indirect effect on regional performance.
 2
 3 Moreover, in the IV regressions the estimated weight of LANG in the KPAT equation is
 4
 5 higher than in the performance equation. This is because in the kind of openness that
 6
 7 matters for acquiring knowledge capabilities – like tapping into wider, typically
 8
 9 international, scientific and technological networks – linguistic skills are relatively more
 10
 11 important. Thus, we can only expect them to weigh less in the direct effect of openness,
 12
 13 which is mostly associated with non-technological factors. We also find a sizable and
 14
 15 significant impact of HRSTE on KPAT. This reinforces our conjecture that HRSTE is
 16
 17 an input to KPAT which then affects regional performance. Density is still important as
 18
 19 a direct effect to regional performance, but in the IV regressions it is not as important as
 20
 21 an effect on the accumulation of technological capabilities.
 22
 23
 24
 25
 26

27 TABLE 4 ABOUT HERE

28
 29 The indirect effect of openness is sizable. We can perform the same exercise that
 30
 31 we performed earlier and look at a one standard deviation in HOTEL and LANG
 32
 33 centered around their sample means. This is 1.592 in the case of HOTEL, as computed
 34
 35 earlier, and $0.213/0.469=0.454$ in the case of LANG. Consider the change in HOTEL
 36
 37 first. Given the estimated parameters in the IV(2) regression in Table 4, the estimated
 38
 39 direct effect of openness on income is the same as earlier, i.e. $0.151*0.997*1.592 =$
 40
 41 0.240 . To obtain the indirect effect we first compute the impact of a one standard
 42
 43 deviation increase in HOTEL on KPAT. This is $0.905*0.539*1.592 = 0.776$. The
 44
 45 indirect impact on income through KPAT is then $0.156*0.776 = 0.121$, or about 50% of
 46
 47 the direct effect. The total (direct plus indirect) impact is 0.361. Since the relative one
 48
 49 standard deviation increase in income centered around its sample mean is 0.272, as
 50
 51 computed earlier, the total impact corresponds to an increase that is almost one-third
 52
 53 higher than the relative one standard deviation increase in income in our sample. If we
 54
 55 add a relative one standard deviation increase in LANG centered around its mean, 0.454
 56
 57
 58
 59
 60

1 computed above, the direct effect is unaffected because the impact of LANG on income
2 in IV(2) is practically zero. The indirect effect is $0.156*0.905*0.461*0.454 = 0.030$.
3
4
5 Thus, the total change in relative income following the one standard deviation increases
6 on the sample means in both HOTEL and LANG is 0.391, which is well above the
7
8 change in income by one standard deviation on the sample mean in our sample.
9
10

11
12 To summarize, our index of openness has a sizable effect on regional per capita
13 income as a proxy for regional labor productivity. First, there is an important direct
14 effect. Openness embeds regions in wider networks and this affects its performance in
15 various ways. The direct effect can take various forms. For example, open regions
16 exhibit greater links with the national or international markets. Therefore, they can
17 capture earlier – and more effectively – shocks to demand. As discussed in Section 2, a
18 good deal of the growth of the Indian, Irish, or Israeli IT industries stemmed from their
19 ability to take advantage, more than other emerging regions, of the growth in the
20 demand for IT by the advanced economies. In turn, this stemmed from their established
21 linkages with such markets in the form of familiarity with the English language, a good
22 deal of expatriates to the US, and especially in the case of Ireland, and partly Israel, the
23 presence of multinational enterprises in the country. As also discussed in Section 2 this
24 may have taken the form of greater exports. However, the direct effect can also take
25 subtler forms, like exposure to international best practices, feedbacks from advanced
26 users, links to better suppliers or access to learning processes.
27
28
29

33
34
35
36
37
38
39
40
41
42
43
44
45
46
47

48 In addition, we find that there is an important indirect effect of openness.
49
50 Openness affects the innovation output of the regions, which then affects their
51 performance. Interestingly, an increase in the linguistic skills of the population has a
52 smaller overall effect than an increase in HOTEL. However, the indirect effect of
53 LANG on regional performance is much higher than its direct effect. This indicates that
54 the language skills of the population are more important for accumulating technological
55
56
57
58
59
60

1 capabilities than for their direct effect on regional performance. This is suggestive of the
2 nature of the links between openness, technology, and performance. Knowledge of
3 languages most likely accounts for the ability to access a wider pool of knowledge
4 assets. Since knowledge is typically produced more efficiently when one has access to
5 wider and better knowledge inputs, our results emphasize the importance of being
6 hooked into wide international networks for both the production of technology and
7 regional economic performance.
8
9
10
11
12
13
14
15
16

17 18 19 20 21 **4.2 Robustness checks**

22 We provide three robustness checks of our results. They are shown in Table 5.
23

24
25 TABLE 5 ABOUT HERE
26

27 We first run our IV(2) regression by employing the English equivalent of LANG
28 (i.e., by considering only people who speak English rather than any other language) and
29 after removing the UK regions. Our empirical results are robust to this specification.
30
31 Interestingly, we now find that the direct impact of openness (α_{OPEN}) is smaller, while
32 the indirect impact of openness (β_{OPEN}) is higher. Moreover, we find that the impact of
33 LANG is higher especially in the KPAT equation. This suggests that the use of English
34 as a proxy for openness reinforces our interpretation of the results, viz. the knowledge
35 of English means that the regions are more embedded into international knowledge
36 networks, and this strengthens the indirect effect of openness and the role of language
37 and communication in affecting it.
38
39
40
41
42
43
44
45
46
47
48
49
50

51 Our second check hinges on the fact that globalization has grown steadily
52 throughout the 1990s. We then expect that the impact of openness on performance will
53 be higher in our second period compared to the first one. In addition, the growing
54 importance of services and less tangible goods suggests that the more intangible
55 components of openness, which we summarized by language skills in the region, have
56
57
58
59
60

1 become more important. At the same time, not only has scientific and technological
2 knowledge grown worldwide during the 1990s, but more countries and regions in the
3 world have become relevant producers of knowledge, technologies, and innovation. As
4 a result, an open region has more opportunities to tap into external knowledge inputs.
5 We then also expect the impact of our index of openness on KPAT to be higher in the
6 second period.
7
8
9
10
11
12
13
14

15 Table 5 presents the results of a joint estimation of (1) and (2) for each of our two
16 periods. Both equations use the same regressors and instruments (appropriately lagged)
17 of the panel estimation. The regional performance equation shows that in 1995-1997 the
18 direct impact of openness, α_{OPEN} , is less than one third of the impact of openness in
19 1998-2000. Moreover, α_{HOTEL} is smaller in the latter period. As predicted, the direct
20 impact of openness has become more important in the second period, and the relevance
21 of communication and more intangible components of the openness index has also
22 increased. Likewise, the impact of openness on KPAT, β_{OPEN} , has increased in the
23 second period, and β_{HOTEL} has decreased. The statistical significance of these
24 coefficients is less sizable than in the panel estimation because of the lower number of
25 observations in each equation. However, the point estimates are in the direction that we
26 are suggesting.
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43

44 In our third robustness check we run our two equations by replacing $\log(Y_{it})$ and
45 $\log(KPAT_{it})$ with their differences from their region average across the two periods.
46 Because of the very large number of regions compared to only two time periods we
47 could not estimate our equations with regional fixed effects. This is the closest attempt
48 to control for regional individual effects. Also, since for a few regions we only had
49 observations in one period, the corresponding net variable was zero. We preferred to
50 include these observations in our equations to keep the same number of observations as
51
52
53
54
55
56
57
58
59
60

1 in the previous equations. When we eliminated them the results did not change. The
2
3 results of this estimation are similar to those in Table 4.
4
5
6
7

8 5. CONCLUSIONS 9

10 This paper contributes to the tradition of studies on the economic performance of
11 regions, and particularly of European region (e.g., Fagerberg *et al.*, 1997; Verspagen,
12 1997; Caniels, 1999; Paci and Usai, 2000). Its empirical results corroborate the key
13 findings of this literature, particularly that R&D, patents, or more generally
14 technological capabilities have a sizable and significant effect on regional economic
15 performance in Europe. In addition, we find evidence of agglomeration economies
16 consistent with the tradition of studies on this matter (e.g. Audretsch and Feldman,
17 1996; Porter, 1998; Swann et al. 1999; Ciccone, 2002; Döring and Schnellenbach,
18 2006). Specifically, we find a positive and significant effect of population density on
19 our measure of regional productivity.
20
21
22
23
24
25
26
27
28
29
30
31
32
33

34 The main contribution of this paper is to link this literature to the growing
35 literature on the importance of “openness” for economic performance. We find that,
36 along with technology and agglomeration, among European regions openness also
37 matters. Moreover, we were careful in trying to pick the effects of openness on
38 performance and not the other way around, or some spurious correlations.
39
40
41
42
43
44
45

46 This has natural policy implications. Particularly, actions aimed at making a
47 region less “provincial” can be quite important. As a first step in this kind of study, we
48 did not distinguish whether openness is produced by spillovers due to mobile and
49 internationalized human capital, the presence of multinational corporations, or other
50 factors. These can be topics for future and more focused research, which require new
51 data collections. However, the experience of some of the fast growing regions of the
52 world today (e.g., the Asian Tigers, Ireland, or Israel) indicates that these factors are
53
54
55
56
57
58
59
60

1 correlated with one another. In short, there may be underlying factors that account for
2
3 the extent to which some regions are more open than others, and we found that these
4
5 factors matter.

TABLES

Table 1. List of variables

Y_{it}	Regional GDP (in PPP and corrected for inflation) over population 25-65 [in 000 euros]
$HOTEL_{it}$	Share of hotels on the population (in 000) of the region
$LANG_{it}$	Share of individuals in the Eurobarometer sample who live in the region, are 27 or more at the beginning of the two periods, and know a foreign language. Proxies for the share of regional population who knows a foreign language (<i>Source: Special Survey on Languages, Eurobarometer 54</i>)
$HRSTE_{it}$	Human Resources in Science and Technology – people who have successfully completed third level education [in 000]
$KPAT_{it}$	Stock of European patent applications computed from the number of annual patent applications in region i using a 0.25 depreciation rate. Initial value of stock for 1989 (1 st year of patent application data in REGIO) obtained as ratio between the number of patent applications in the region and the depreciation rate 0.25
$DENS_{it}$	Population density = Population [in 000] / Area [in Km ²]
POP_{it}	Population [in 000]
MTW_{it}	Motorways length [in Km]
$TOURISM_{it}$	Share of annual arrivals of non-residents in the region who are accommodated in establishments other than hotels, e.g. campings or hostels
<i>Country dummies</i>	Dummies for European country of the region: AT, BE, DE, ES, GR, FR, IT, NL, PT, UK. Default dummy groups Denmark and regions from Finland, Ireland, and Sweden, which had too few regions to make separate country dummies.
<i>Time dummy</i>	Dummy equal to 1 for 1998-2000 and zero otherwise
Additional variables used as instruments	
$LANG18_{it}$	Like LANG, but only individuals who learned the second language before they were 18 (<i>Source: Special Survey on Languages, Eurobarometer 54</i>)
$UNILAB95_i$	Number of university research laboratories in the region in 1995 (<i>Source: European R&D database, Reed Elsevier Publisher, 1996</i>)
$PASS_{it-4}$	Number of airplane passengers embarked and disembarked in the region lagged four periods (1986-1988 for 1998-2000 and 1983-1985 for 1995-1997 [in 000])
POP_{it-2}	Population lagged two periods (1992-1994 for 1998-2000 and 1989-1991 for 1995-1997) [in 000]
$AREA_i$	Area of region [in Km ²]
MTW_{it-2}	Motorways length lagged two periods (1992-1994 for 1998-2000 and 1989-1991 for 1995-1997) [in Km]

i = regions, t = two periods, 1995-1997 or 1998-2000. Annual variables averaged over the three years in the period. Sources of data is Eurostat REGIO, unless otherwise indicated.

*** p < 0.01, ** p < 0.05, * p < 0.10. Heteroskedastic consistent Standard Errors in parenthesis. Instruments, see Table 3. (§) LANG defined as in Table 2 but for people who speak English rather than any other language. All the other variables (including instruments) are unchanged. (^) Because of few observations, in 1995-1997 we lumped the dummies for BE, NL, PT in the default category. Similarly for AT in 1998-2000. (+) Dependent variables are the OLS residuals of a regression that employs all the regional dummies as covariates.

12
13
14
15
16
17
18 ¹ See however Shang-Jin and Yi (2001).

19
20 ² We could not use employment in the denominator because it had many missing observations in REGIO.
21
22 We replaced it by population in the workforce age. Since, as we shall see, our regressions are log-log, we
23
24 can always interpret our estimated parameters as impacts on the region GDP. To be sure, this may also
25
26 raise the issue that regional GDP is the result of many other influences beyond labor productivity in a
27
28 narrow sense. Since we do not have very many observations we could not employ a vast array of controls.
29
30 However, time and country dummies can take care of these factors, especially because most of the
31
32 controls that we would need are likely to be correlated with one another.
33

34
35 ³ Since Eurobarometer provides the date of birth of the interviewees, we computed the shares of
36
37 individuals who were 27 or older in 1995 and 1998. However, we cannot take into account the individuals
38
39 who died. Since LANG and LANG18 are shares, the time period is small, and the largest variation in our
40
41 data is across regions and not over time, this error is negligible.
42

43
44 ⁴ We also experimented with the other controls discussed in the previous section, including a measure of
45
46 capital formation in the region. They turned out to be insignificant in both equations, and they produced
47
48 no appreciable change in the results.
