15 Abstract

16
17 We investigate and compare the spatial distribution of manufacturing activity
18 and its determinants in Belgium, Ireland, and Portugal using comparable,
19 exhaustive micro-level data sets. We find some similarities between Portugal
20 and Belgium, but little for Ireland. Moreover, there is some evidence that
21 forward and backward linkages, R&D activity, and labour market pooling of
22 skilled labor can be important determinants of agglomeration, although this
23 crucially depends on the country examined.

Résumé

Dans cet article, nous analysons et nous comparons la répartition spatiale des activités manufacturières et de leurs déterminants en Belgique, en Irlande et au Portugal, en utilisant des ensembles exhaustifs de microdonnées comparables. Nous trouvons des similitudes entre le Portugal et la Belgique mais peu pour l'Irlande. De plus, il s'avère que des liens avant et arrière, d'activités de R&D et de mise en commun du marché des emplois qualifiés peuvent être des déterminants importants d'agglomération bien que cela dépende étroitement du pays analysé.

17
18 Abstract

19
20 Wir untersuchen und vergleichen die räumliche Verteilung von produzierender
21 Arbeit und ihren Determinanten in Belgien, Irland und Portugal mit Hilfe von
22 vergleichbaren, umfassenden Datensätzen auf Mikroebene. Wir stellen einige
23 Ähnlichkeiten zwischen Portugal und Belgien fest, jedoch wenige für Irland.
24 Darüber hinaus weist einiges darauf hin, dass die Vorwärts- und
25 Rückwärtsverbindungen, die Forschungs- und Entwicklungsarbeit sowie die
26 Konzentration von Fachkräften auf dem Arbeitsmarkt wichtige Determinanten
27 für eine Agglomeration darstellen können, wobei dies aber im Wesentlichen
28 vom jeweils untersuchten Land abhängt.

49
50
51 Abstract

52
53 Con ayuda de un grupo de datos comparables y exhaustivos a nivel micro,
54 investigamos y comparamos la distribución espacial de la actividad manufacturera y
55 sus determinantes en Bélgica, Irlanda y Portugal. Observamos algunas similitudes
56 entre Portugal y Bélgica pero pocas con Irlanda. Asimismo existen evidencias de que
57 los vínculos hacia delante y atrás, la actividad de I+D y la concentración de mano de
58 obra cualificada en el mercado laboral pueden ser determinantes importantes de
59 aglomeración si bien esto depende básicamente del país que sea analizado.

SECTION I: Introduction

It has long been recognized that economic activity is unevenly distributed across space. For example, Fujita and Thisse (2002) illustrate this feature by pointing out that the Japanese core regions with a mere 0.18 per cent of the total area account for about 29 per cent of East Asia's GDP. There is also plenty of similar evidence for other regions in the world, for instance, the Blue Banana in Europe, the Manufacturing Belt in the US, industrial districts in Italy (Pyke et al. (1990)), Route 128 and Silicon Valley in the US (Saxenian (1996)). But are these examples the rule or the exception? And how general and how strong is the tendency of industries to agglomerate?

While a now large body of theoretical studies have provided micro-foundations to explain why agglomeration may arise, theorists have pointed to the necessity of “buttressing [their] approach with empirical work” (Fujita et al. (1999, p.345)). Ideally, empirical studies would rely on micro level data in order to illustrate the mechanisms

1
2
3 explaining how and why activities concentrate across space, and also provide results that
4 are comparable across countries. Unfortunately, up to now, existing empirical studies on
5 these matters have either used micro level data while being limited to one country,¹ or
6 have used aggregated data at the macro/regional level in order to obtain cross-country
7 evidence.² The present study is an attempt to push the analysis a step further by
8 reconciling the use of micro level data and the need for comparative cross-country
9 evidence. The objective of the present study is to provide thus a rigorous analysis of
10 whether, how, and why agglomeration patterns of similar sectors differ across three
11 European countries, namely Belgium, Ireland and Portugal. Specifically, we provide
12 evidence for the agglomeration of manufacturing activities across space using exhaustive
13 and comparable micro-data for three different countries, namely Belgium, Ireland, and
14 Portugal.

31 This type of empirical work is arguably important for the realm of location theory since it
32 provides results that can help to gauge the relevance (or to invalidate) of existing
33 theoretical models, as well as to indicate areas in which further theoretical analysis is
34 called for. Importantly, the type of study undertaken here can also allows one to check if
35 industry agglomeration forces are invariant across countries – in this case empirical
36 research on different countries would be just about studying the same economic
37 mechanism with different data - or differ significantly across countries – in this case
38 empirical analysis should devote more attention to explaining country-specific features.
39 In particular, regarding the latter approach, one should note that the three countries
40 under scrutiny arguably make for an interesting comparison group. On the one hand,
41 these countries differ in aspects that may constitute important factors of the process of
42 agglomeration. For example, while Portugal and Ireland are peripheral countries, Belgium
43 is located in the core of the EU. Much of the theoretical literature about the impact of
44 economic integration in the EU context has provided numerous results concerning the

1
2
3 influence of economic integration on the location of economic activities.³ Moreover, the
4
5 countries under scrutiny differ considerably in terms of industrial expenditures devoted
6
7 to R&D, the benefits of which have long been claimed to be bounded geographically.⁴
8
9 Finally, Belgium, Ireland, and Portugal also have rather varied industrial labour force
10
11 compositions as well as quite different institutional labour market settings which, for
12
13 instance, may influence labour mobility and, by the same token, the location of economic
14
15 activities.⁵ On the other hand, these countries are similar in aspects that may influence
16
17 agglomeration. For instance, they are all members of the European Union. This fact
18
19 implies, inter alia, that they all have implemented the European Single Market Program,
20
21 which provoked a strong need for modernisation and adaptation to increased
22
23 competition with a consequent impact on the distribution of economic activities.
24
25 Moreover, these countries, because they have small open economies, have strong export-
26
27 led sectors, which may well manifest itself in similar agglomeration patterns.
28
29
30
31
32

33
34 Last, but not least, our study is important to the location theory because, as Combes
35
36 and Overman (2005) have recently pointed out, "a deeper understanding of the
37
38 similarities among industries of European countries may have profound implications for
39
40 on going research because one needs to be able to understating those patterns with
41
42 reference to a large body of existing literature (mostly based on US data". To our
43
44 knowledge, this is the first study that explicitly addresses the important issue of cross-
45
46 country comparison using a unified microeconomic dataset.
47
48
49
50
51
52

53
54 Our analysis of the patterns of agglomeration in these three countries relies on the
55
56 index developed by Ellison and Glaeser (1997) - from now on referred to as the EG
57
58 index. Importantly, this index, unlike more traditional measures, has explicit theoretical
59
60 foundations and is based on (plant-level) microeconomic behaviour. Moreover, once

plant-level data is available, Ellison and Glaeser (1997) claim “the index is designed to facilitate comparisons across industries, across countries, or over time” (Ellison and Glaeser (1997), p.890). Despite this assertion, no explicit comparative study across countries has been undertaken so far. Rather, existing applications of the EG index (and of its extensions) have been limited to the intersectorial comparisons across studies using different aggregation levels (see Ellison and Glaeser (1997) for the US as well as the study by Maurel and Sédillot (1999) for the French case). An important limitation of this index is that it is based on the distribution of activity over discrete spatial units and, consequently, if agglomeration forces are not geographically bounded and extend to neighbouring areas, the index will be biased downwards (and detect less agglomeration) the smaller the size of the area considered. This issue relates to the so-called Modifiable Area Unit Problem (MAUP) and more specifically to the choice of the appropriate spatial unit. We thus also use the Moran's I statistic to reduce this scale problem by selecting a high spatial level when autocorrelation is detected in small spatial units. While the Ellison and Glaeser index is complemented with an indicator of spatial autocorrelation, the Moran I's statistic, its measurement of agglomeration is built on a discrete version of space. Since space differs from one country to another, one cannot exclude that marked agglomeration similarities or dissimilarities among countries reflects some spurious effect due to the application of the EG index to countries with different internal geographies⁶.

Of course, whatever patterns of concentrations are established, it is also important in any analysis to seek to understand the underlying forces driving these. To this end, we gather a consistent set of explanatory variables across countries and sectors aiming to proxy the different theoretical explanations as to why agglomeration of economic activities occurs. The main theoretical arguments can roughly be classified according to so-called Marshallian externalities (for a survey, see Duranton and Puga, 2004). More

1
2
3 specifically, Marshall's first theory claims that the existence of scale economies in input
4 production could induce firms to locate close to their inputs. Elaborating on Marshall's
5 concept, the New Economic Geography literature stipulates that such input-output
6 linkages, alongside increasing returns, may give firms an incentive to locate near markets
7 (and near their suppliers) in order to save on transport costs. In this context, market-size
8 effects expand in a self-reinforcing process of agglomeration as if plants agglomerate for
9 the reason stated above, this will in turn attract more firms (see Fujita and Thisse, 2002).
10 Labor market pooling may also be an agglomerative force because industrial
11 agglomeration should encourage the formation of thick local labor markets so that
12 employees could find it easier to match with employers and vice-versa (see Helsley and
13 Strange, 1990, and Monfort and Ottaviano, 2000). Finally, knowledge spillovers could
14 lead to agglomeration because they can generate externalities that are bounded
15 geographically, increasing the productivity of firms in the region where the new
16 economic knowledge was created. Firms may thus locate where they are likely to learn
17 from other firms (see Henderson 1974, 1988, and Glaeser 1999).

35
36
37
38
39
40

41 Nevertheless, despite these numerous theoretical contributions, evidence
42 concerning the determinants of agglomerations also remains scarce and relatively recent.
43 In particular, among the few, Dumais et al. (2002) decompose the index developed by
44 Ellison and Glaeser (1997) to determine the contribution of plant entry and exit on
45 agglomeration. Holmes and Stevens (2002) also decompose an index of agglomeration,
46 isolating the impact of establishment scale on agglomeration. Kim et al. (2000),
47 Rosenthal and Strange (2001) and Teixeira (2002), in contrast, shed light on the causes of
48 agglomeration by using standard parametric estimation techniques. In an approach
49 similar to these latter three studies we, in the current paper, also try to disentangle the
50
51
52
53
54
55
56
57
58
59
60

different sources of agglomeration found by running parametric estimations and using as dependent variable the EG index and a number of other data intended to proxy the various theoretically proposed determinants of agglomeration.

The rest of the paper is organized as follows. In Section II, we provide some details about the tools being used to analyze the patterns of agglomeration. Section III proceeds with a description of our data sources. Observed patterns of agglomeration using these data and tools are presented and discussed in Section IV. Section V explores the sources of agglomeration econometrically. Section VI concludes.

SECTION II: Measuring Agglomeration

Ellison and Glaeser (1997) proposed an index of spatial concentration, which has the desirable feature of neutralizing the possible influence of industrial concentration resulting from internal economies of scale. Its expression for a particular industry i is given by:

$$\gamma_i = \frac{G_i - (1 - \sum_c x_c^2) H_i}{(1 - \sum_c x_c^2)(1 - H_i)}$$

where G_i is a measure of geographic concentration, defined as the sum of squared deviations of s_{ic} (the share of industry i 's employment in area c) to x_c (the share of aggregate manufacturing employment in area c), i.e., $G_i = \sum_c (s_{ic} - x_c)^2$. The term $H_i = \sum_j z_{ij}^2$ represents the classical Herfindahl-Hirschman index defined as the sum of squared plant employment shares of industry i , with $j=1\dots N$, the plant-indices. In a situation where there is random location, random market shares and the number of plants in a sector increases, H_i tends to 0. Thus the EG index tends to the measure of

1
2
3 geographic concentration G_i times an industry invariant term, and its mathematical
4
5 expectation tends to 0.
6
7

8
9 An important aspect of the EG index with respect to the current study is its
10 distinctive feature of being comparable across time and sectors regardless of plants' size
11 distribution. A further important property of the EG index lies in its theoretical
12 foundation as it is based on a location model, i.e., where firms choose location following
13 a Bernoulli process according to the presence of natural advantage and/or spillovers. The
14 EG index thus asks the question whether concentration is greater than would be
15 expected to arise randomly.
16
17
18
19
20
21
22
23

24
25 However, it must also be noted that the EG index suffers from two major drawbacks:
26
27 Firstly, as noted by the authors themselves, the major theoretical limitation is that the
28 EG index cannot distinguish between spillovers and natural advantages to explain the
29 reasons why plants agglomerate. This is simply due to the fact that in their location
30 model there is an observational equivalence between natural advantages and spillovers. In
31 this regard one should add that it also is not able to distinguish home market effect or
32 any other mechanism, other than scale economies, leading to agglomeration. Following
33 the original authors and other subsequent researchers using the EG index, we are thus
34 also not able to investigate this aspect any further.
35
36
37
38
39
40
41
42
43
44
45

46
47 A second and potentially more important issue is related to the choice of spatial unit,
48 the so-called *Modifiable Areal Unit Problem* (MAUP).⁷ Theory tells us that pecuniary
49 externalities may reach wider geographical areas than technological externalities (see for
50 instance Lamorgese and Ottaviano (2002) for a discussion on this issue). This seems thus
51 to imply that while all externalities are important at small spatial scales only pecuniary
52 externalities play a decisive role on agglomeration at high spatial scales. Clearly, because
53
54
55
56
57
58
59
60 these externalities have different geographic scales, a much denser agglomeration may

1
2
3 result from technological externalities that require strong interactions between agents in
4
5 activities where information is more important than from pecuniary externalities that can
6
7 also arise through inter-regional trade.
8
9

10 Since the EG index is based on the distribution of activity over discrete spatial units and
11
12 if, as discussed by Ellison and Glaeser (1997), agglomeration forces are not
13
14 geographically bounded and extend to neighbouring areas, then the index will be biased
15
16 downwards (and detect less agglomeration) the smaller the size of the area considered.
17
18 The use of Moran's I is a good solution to reduce the scale problem by choosing the
19
20 regional rather than the local level when autocorrelation is detected⁸. Spatial
21
22 autocorrelation considers the possibility that observations of a variable (here the location
23
24 of industries) may not be independent across space. In this regard, clusters of events,
25
26 people, or facilities are likely to be affected by positive spatial autocorrelation, whereas
27
28 negative spatial autocorrelation refers to arrangements where people, events or facilities
29
30 are dispersed.
31
32
33
34
35
36
37
38
39

40 The Moran statistic compares the value of a continuous variable at any location with
41
42 the value of the same variable at surrounding locations. Formally, it is defined as:

$$43 I = \frac{N}{S} \cdot \frac{\sum_c \sum_{c'} w_{cc'} (x_c - \bar{x})(x_{c'} - \bar{x})}{\sum_c (x_c - \bar{x})^2}$$

44
45 with $S = \sum_c \sum_{c'} w_{cc'}$, $\bar{x} = \sum_c x_c / N$ and $c \neq c'$, where x_c represents the value of the
46
47 observation in region c , N is the total number of observations, \bar{x} is the mean of the
48
49 variable across all observations and $w_{cc'}$ is a weight between region c and region c' . Our $w_{cc'}$
50
51 has been set equal to 1 when regions c and c' are contiguous and 0 elsewhere. Values of I
52
53 significantly larger than the expected value of the Moran statistic, $E[I] = -1/(N-1)$,
54
55
56
57
58
59
60

1
2
3 indicate positive spatial association, i.e., similar values are more spatially clustered than
4
5 could be caused purely by chance, whereas values of I smaller than $E[I]$ indicate negative
6
7 spatial association.
8
9

10 11 12 13 SECTION III: Data 14

15
16 In order to compute a comparable EG index across our three countries we utilise
17
18 three different data sources. For Ireland we draw on information from the Forfàs
19
20 Employment Survey, for Belgium we used data on employment from the Social Security
21
22 database, and for Portugal data originates from the Ministry of Employment. Detailed
23
24 description of our various data is given in the Appendix. In choosing the year of our
25
26 analysis, we used the latest year that was common to all our data, namely 1998.
27
28
29

30
31 An important task when undertaking a cross-country study is to unify the data.
32
33 Essentially, we had to take care of two dimensions: the sectorial and the spatial one. In
34
35 terms of the sectorial classification issue, data was either in NACE (Nomenclature
36
37 générale des activités économiques dans les Communautés européennes - General
38
39 Industrial Classification of Economic Activities within the European Communities) or in
40
41 ISIC (International Standard Industrial Classification) classification, depending on the
42
43 country in question. Portuguese data was readily available as ISIC Rev. 2 and it was
44
45 converted into ISIC Rev.1, while Irish data was available at NACE Rev.1 at a four-digit
46
47 level of disaggregation. For Belgium, data was originally collected according to the
48
49 NACE-BEL sectors, which, apart from some small differences, very closely follow
50
51 NACE Rev.1 classification. In order to work with a common set of sectors we made use
52
53 of the concordance tables between ISIC and NACE available from Eurostat (the
54
55 European statistics office) in order to convert the Irish and Belgian data.⁹ Four-digit ISIC
56
57 sectors roughly corresponded to three-digit NACE sectors, for which Belgian and Irish
58
59
60

1
2
3 data had been collected so we took ISIC Rev.1 as the common classification for which
4 no changes for Portugal data was required.¹⁰ After having put this data together and
5
6
7
8 keeping only those sectors that were common to the three countries, we ended up with
9
10
11 63 common four-digit ISIC sectors, which represent between 85 to 95 per cent of total
12
13 manufacturing employment for these three countries.
14

15
16 In terms of the choice of spatial units the task of unification was more
17
18 cumbersome. The only common spatial unit at the European level is the *Nomenclature des*
19
20 *unités territoriales statistiques/Nomenclature of territorial units for statistics* (NUTS), where NUTS
21
22 is a five-level hierarchical classification (three regional levels and two local levels).¹¹
23
24 However, the regional classification available to us did not always correspond to this
25
26 spatial classification, especially for Ireland. As a result, our choice of spatial units was
27
28 essentially restricted by data availability. In the end two spatial units were used, one
29
30 regional and one local. For Belgium, NUTS3 (43 *arrondissements*) and NUTS5 (589
31
32 *communes*) spatial units have been selected. In the Irish case, at the regional level, NUTS4
33
34 (27 *counties*) spatial units were chosen, whereas for the local level an intermediate level
35
36 between NUTS4 and NUTS5 (504 *townships*) spatial units was used.¹² Finally, for
37
38 Portugal, no analogous regional level was available, therefore we used a somewhat
39
40 rougher spatial unit than NUTS3 for the regional level, namely districts (18 *distritos*), and
41
42 for the local level NUTS4 (275 *concelhos-municipos*).¹³
43
44
45
46
47

48
49 It is also worth noting that some descriptive statistics on the sectoral share of
50
51 employment show that specialization patterns are rather different across countries.
52
53 Portugal appears to be more specialized in more traditional industries like textiles and
54
55 wood industries, while Ireland highlights an important share of its employment in high-
56
57 tech industries such as machinery equipment. The picture is, in contrast, quite mixed for
58
59 Belgium, as shown in Table 2..
60

SECTION IV: Patterns of Agglomeration

As noted earlier, in terms of calculating the EG index we have two spatial units at our disposal, the regional and the local level, and we initially calculated the EG index using both of these. Doing so we found that the correlation between EG indices at the regional level and at the local level is relatively high in Belgium and in Portugal (statistically significant spearman rank correlation coefficients of 0.7 and 0.5, respectively), but very low for Ireland (0.1 and not significant)¹⁴. This would suggest that the underlying pattern of agglomeration differs strongly, depending on the spatial units employed, and perhaps that the analysis should have proceeded using both comparatively. However, as noted earlier, one concern with regard to the EG index is the potential bias introduced via spatial autocorrelation, which is likely to be larger for smaller units. To examine this we calculated in Table 3 the Moran index for local spatial units using binary decay effects based on contiguity matrices. Except for Ireland, one finds that about a third of all sectors are characterised by positive and statistically significant spatial autocorrelation.¹⁵ Clearly this represents a non-negligible number of sectors and suggests that some care should be taken when interpreting EG index results obtained from *local* spatial units. We thus henceforth proceed using the regional rather than the local level as our spatial unit.

Our results on the EG index at the regional level for the three countries are given in Tables 4-6. When comparing results among countries, a striking feature is that Portugal's level of agglomeration is much higher than for Belgium and Ireland. More precisely, the weighted average EG index is 0.027 for Belgium and 0.038 for Ireland, whereas for Portugal it stands at 0.133.¹⁶ In the case of Portugal, one obvious reason why the average EG index is higher is related to the fact that the industrial concentration, measured by

1
2
3 the Herfindahl-Hirschman index, is quite low in Portuguese industry (see Barrios et al.,
4
5
6 2005).
7

8
9 Whereas the Portuguese aggregate level of concentration clearly departs from the
10
11 Belgian and Irish ones, the picture changes when it comes to comparing the patterns of
12
13 agglomeration of individual sectors. Taking the rank correlations in Table 7, Ireland
14
15 appears to clearly diverge from Portugal and Belgium, whereas the two latter have a
16
17 positive (although not very high) and statistically significant spearman rank correlation
18
19 coefficient. Several explanations can be put forward possibly explaining this result. First,
20
21 whereas Belgium and Portugal have roughly similar population levels of around 10
22
23 million, Ireland has 3.5 million. Smaller population size in turn implies fewer plants,
24
25 meaning that agglomeration patterns are harder to disentangle for particular sectors. Put
26
27 differently, few plants imply that the marginal impact of one plant's location on the EG
28
29 index is more important, which could well explain our results. A second explanation
30
31 relates to fact that Ireland is an island, hence the centrifugal and centripetal forces at
32
33 work are likely to act differently. In particular, cross-border effects, which are likely to be
34
35 important particularly for Belgium, but also to a lesser extent for Portugal, are obviously
36
37 not relevant in the case of Ireland. That is, Belgium is located at the heart of Western
38
39 Europe and is geographically close to countries such as France, Netherlands, and
40
41 Germany with intense trade relationships with all of these. One thus could easily expect
42
43 that industry clusters exist across borders, an example of which are the traditional steel
44
45 industries, which are common to French and Belgium bordering regions.
46
47
48
49
50
51

52
53 Another feature, common to both Ireland and Portugal, is the peripheral location
54
55 with respect to the rest of Europe. Coupled with the fact that these two countries
56
57 entered the European Common Market relatively late (in 1973 for Ireland and 1986 for
58
59 Portugal), one might thus expect to find common features of agglomeration across these
60

1
2
3 two countries. In particular, both countries have strong export-led economies, as it is
4 generally the case of small open economies. As has been shown elsewhere, exporting
5 firms tend to be larger on average and have different patterns of agglomeration (Bernard
6 and Jensen (1995), Holmes and Stevens (2002)). It should also be noted that FDI has
7 played a large role with multinationals increasingly choosing Ireland in order to get access
8 to the EU market (Barry and Bradley (1997)). Multinationals' presence may, in turn, have
9 influenced the location pattern of industries if externalities arise between domestic and
10 foreign plants (see Barrios et al. (2006) for evidence concerning Ireland).

11
12
13
14
15
16
17
18
19
20
21
22 Comparing the sectorial indices individually within and across countries also reveals a
23 number of interesting patterns. As shown in Tables 4-6, the most agglomerated sectors
24 in Belgium and Portugal are Misc. Products of Petroleum and Coal (3540), Shipbuilding
25 and Repairing (3841). This may not be very surprising given that this sector is obviously
26 very dependent on location. It thus is supportive of Heckscher-Ohlin type of models,
27 where trade and specialization depends on the factor endowments of countries/regions.
28 We also find that traditional sectors as Tanneries and Leather Finishing (3231),
29 Manufacture of Wood and Cork Products NEC (3319), Jewelry and Related Articles
30 (3901), Pottery, China and Earthenware (3610), Knitting Mills (3213), Manufacture of
31 Carpets and Rugs (3214) appear to be highly agglomerated, especially in Portugal, but
32 also in Ireland. Ellison and Glaeser (1997) and Maurel and Sédillot (1999) find similar
33 results for the US and France, respectively. In contrast, we discover that sectors related
34 to food and beverages tend to be dispersed. This is particularly true for Manufacture of
35 Dairy Products (3112), Slaughtering, Preparing and Preserving Meat (3111), Grain Mill
36 Products (3116), and Manufacture of Food Products, N.E.C. (3121) in Belgium and
37 Portugal, and to a lesser degree, in Ireland. As a potential explanation one should note
38 that since most of these products are perishable, it is likely important for their producers
39 to locate close to their consumption market. In a way, these results also confirm the
40

55
56
57
58
59
60

1
2
3 market potential story, popular in the economic geography literature. Accordingly,
4 industries will choose their location by taking into account distance to and size of the
5 customers. Ideally, production would then have to settle near each consumer. However,
6 given that there are indivisibilities in production, there is also a trade off that producers
7 have to solve - the less constraining indivisibilities are, the more dispersed activities will
8 be relative to all other activities.
9

10
11 A further interesting observation is related to high-tech sectors.¹⁷ We find that
12 high-tech sectors have a lower average EG index than the rest. This result is consistent
13 across the three countries under scrutiny. One should note that similar results have also
14 been found using German (Alecke et al. (2003)) and UK data (Devereux et al. (2004)).
15 Three factors, not necessarily mutually exclusive, may explain such a finding. First, the
16 widely held belief that well known high-tech clusters, such as Silicon Valley in the US or
17 Sofia Antipolis in France, are representative of general agglomeration processes is untrue.
18 A second explanation derives from the possibility that our sectorial disaggregation is too
19 rough to capture very specific high-tech clusters.¹⁸ Finally, it may be due to the fact that
20 our choice of spatial unit is not appropriate to identify high-tech clusters. Indeed, taking
21 the Belgian local level spatial units, the average high-tech EG index is 0.0035, and 0.026
22 for the non high-tech sectors. Thus, whereas for non high-tech sectors, the EG index has
23 been halved, it has tripled for high-tech sectors. Still, agglomeration of high-tech sectors
24 remains far below the rest of the manufacturing industry.
25
26

48
49

50
51 Ellison and Glaeser (1997) use a non-statistically based value range of the EG index
52 according to which they classify sectors as not very concentrated (smaller than 0.02),
53 relatively concentrated (between 0.02 and 0.05), and highly concentrated (larger than
54 0.05). However, using the variance of the index across sectors it is straightforward to
55 check whether sectors are statistically significantly concentrated by using the two
56
57
58
59
60

1
2
3 standard deviation rule. The two-standard deviation rule supposes the studied random
4
5 variable is roughly normal, so that 95 % of its realizations are around the expectation,
6
7 and in the interval limited by two standard deviations, below or over it. More precisely,
8
9 since the expected value of the EG index is zero one can check whether the absolute
10
11 values of it for an individual sector is larger than twice the standard deviation of the
12
13 index under the null hypothesis of random location. Since Ellison and Glaeser (1997)
14
15 give the analytic expression of the variance of their index, it seems quite obvious to use
16
17 this rule. The main thing is to use the correct variable: The EG mean and its analytical
18
19 variance hold under the hypothesis of random distribution of the firms of a sector.
20
21
22
23
24
25

26 We denote the significant sectors in this regard using an asterisk in Tables 4-6.
27
28 Accordingly, about 25 per cent of the EG indices are found to be significant in the Irish,
29
30 49 per cent in the Belgian, and 75 per cent in the Portuguese case.¹⁹ One may want to
31
32 note that in this regard the number of significant sectors rises with population size of the
33
34 countries. Also unreported results on the standard deviations reveal that the variance of
35
36 the EG indices decreases with country size. This result immediately proceeds from the
37
38 expression of the variance of G_i used by Ellison and Glaeser (1997, p.907), which
39
40 increases with the Herfindahl-Hirschmann index. Thus, as smaller countries tend to have
41
42 higher industrial concentration due to fewer firms, they will also have larger Herfindahl-
43
44 Hirschmann indices. As the variance of the EG index depends positively and linearly on
45
46 the variance of G_i , everything else being constant, smaller countries will have a larger
47
48 variance of their EG indices. This result is consistent with unpublished results on Italy,
49
50 where about 90 per cent of the EG indices turn out to successfully pass the two standard
51
52 deviation rule.²⁰ The same is also true for Maurel and Sédillot (1999) who work on
53
54 French data and find that for their index (which is very close to Ellison and Glaeser's),
55
56 270 out of 273 sectors are statistically significant.

5
6 SECTION V: The Determinants of Agglomeration
7
8

9 As noted in the introduction, there are many theoretical but few empirical analyses of
10 the determinants of agglomeration. To provide an empirical analysis of the determinants
11 of agglomeration for our three countries we proceeded in the spirit of the studies of Kim
12 et al. (2000), Rosenthal and Strange (2001), and Teixeira (2002) and estimate a simple
13 regression where the EG index is regressed on a number of variables intended to proxy
14 the various theoretical explanations put forward in the theoretical literature on
15 agglomeration. A major issue in doing so is to assemble the desired control variables
16 using comparable data across countries and we use mostly Eurostat data in this regard.²¹
17
18
19
20
21
22
23
24
25
26

27 Our chosen explanatory variables are as follows:
28
29

30 Total purchases of goods and services (total inputs): this variable, expressed in millions
31 of Euros, includes the value of all goods and services purchased during the accounting
32 period for resale or consumption in the production process (excluding capital goods).
33 The goods and services concerned may be either resold with or without further
34 transformation, completely used up in the production process or, finally, be stocked..
35 This variable is intended to capture the forward and backward linkages that have become
36 important in the so-called New Economic Geography type models of agglomeration (see
37 Fujita and Thisse, 2002). Accordingly, producers may want to choose locations that have
38 good access to large markets and to suppliers of intermediates, while a concentration of
39 producers tends to offer a large market and a good supply of inputs and consumer
40 goods, hence attracting new producers and new consumers. A positive effect on
41 agglomerations is thus expected from this variable.
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56

57 Sectorial share of skilled works: this variable measures the percentage of the total
58 population that has obtained a higher education diploma and stems from the respective
59
60

1
2
3 national data sources. It is intended to capture labor pooling effects, which is viewed in
4
5 the literature as an agglomerative force because it allows for easier matching between
6
7 employers and employees (see Helsley and Strange, 1990 and Monfort and Ottaviano,
8
9 2000). An increasing effect on agglomeration is thus expected from this variable.
10
11

12
13 Total intra-mural Research and Development expenditure: this variable is expressed in
14
15 millions of Euros. Intra-mural expenditures are all expenditures for R&D performed
16
17 within the unit, regardless of the source of funds. It must be distinguished from
18
19 expenditures for a wide range of related activities. The following are therefore excluded:
20
21 expenditures on education and training; expenditures on other scientific and
22
23 technological activities; expenditures on other industrial activities; expenditures on purely
24
25 financing activities. Intra-mural expenditures are valued at production cost and include all
26
27 operating costs including the labour cost and capital expenditure. R&D typically captures
28
29 knowledge spillovers. It has been shown elsewhere (see for instance Audretsch and
30
31 Feldman (1996), Feldman and Audretsch (1999), Bottazzi and Peri (2003) and Jaffe et al.
32
33 (1993)) that knowledge spillovers could lead to agglomeration because they may generate
34
35 externalities that are bounded geographically, increasing the productivity of firms in the
36
37 region where the new economic knowledge was created. Hence, one might expect R&D
38
39 intensive sectors to concentrate in order to fully benefit from these knowledge spillovers.
40
41
42
43
44

45
46 Purchases of energy products: this variable, expressed in millions of Euros, includes
47
48 energy products only if they are used as fuel, and hence excludes energy products
49
50 purchased for resale without transformation. To derive their index, Ellison and Glaeser
51
52 (1997), start from a model, where agglomeration either results from externalities or
53
54 common natural advantages. Although scholars have mainly been interested in the
55
56 former explanation in order to provide a rationale for Silicon Valley-type of
57
58 agglomerations, natural advantages play a crucial role in explaining the distribution of
59
60

1
2
3 manufacturing activity, especially when the concerned industries are natural resources
4 intensive. For instance, Ellison and Glaeser (1999) show that for the US manufacturing
5 activity, about 20 per cent of observed geographic concentration can be explained by a
6 small set of natural advantages in the United States. Here we consider energy as a generic
7 variable to account for natural advantages. Ideally, one would have liked to include
8 purchases of natural resources as well, but no comparable data is available for the three
9 countries. Note however that in Ellison and Glaeser (1999), they use 3 energy variables
10 (electricity, coal, gas) in their regression that are all statistically significant.

58
59
60
Gross investment in tangible goods: expressed in millions of Euros. Included are new
and existing tangible capital goods, whether bought from third parties or produced for
own use (i.e., capitalised production of tangible capital goods), having a useful life of
more than one year including non-produced tangible goods such as land. Purchased
goods are valued at purchase price, i.e. transport and installation charges, fees, taxes and
other costs of ownership transfer are included. Own produced tangible goods are valued
at production cost. The introduction of this variable follows the same idea as for the
purchase of inputs and hence one would have an a priori positively expected impact on
agglomeration.

Gross investment in machinery: this variable, available in millions of Euros, covers
machinery (office machines, etc.), special vehicles used on the premises, other machinery
and equipment, all vehicles and boats used off the premises, i.e. motor cars, commercial
vehicles and lorries as well as special vehicles of all types, boats, railway wagons, etc.
acquired new or second hand during the reference period. Current maintenance costs are
excluded.

Average plant size: this is the ratio of the number of persons employed (per 1000) by the
number of enterprises (i.e., all units active during at least a part of the reference period).

1
2
3 In a recent contribution, Holmes and Stevens (2002) show that there is a strong link
4
5 between plant size and agglomeration. Plant size may also be interpreted as a proxy for
6
7 the presence of increasing returns to scale, which are central in the models of the New
8
9 Economic Geography.
10
11

12
13
14
15
16 As countries are of very different sizes, all variables listed above have been weighted
17
18 by the number of workers in each sector of the individual countries. We also
19
20 experimented with total production weights, but this led to qualitatively analogous
21
22 results. One should note that for some variables and some countries, information at the
23
24 four-digit sectorial level was not available so that we had to fill these gaps by using their
25
26 three-digit counterparts. Details of this are provided in the data appendix.
27
28

29
30 We first used simple OLS for each of our three country samples separately, as
31
32 shown in Table 8. The first notable feature of these is that our econometric specification
33
34 explains little for Ireland, displaying a very a low R-squared and insignificance for all
35
36 control variables of interest.²² In contrast, the R-squared is substantially higher for both
37
38 Belgium and Portugal. Nevertheless, for Belgium only total input purchases is
39
40 significant, displaying the a priori expected positive sign. A similar result on purchased
41
42 inputs is also found for Portugal, suggesting that backward linkages may be important.
43
44 For Portugal we also find that R&D expenditures play a significant positive role in
45
46 explaining agglomeration, thus indicating that there are benefits to agglomerating in
47
48 sectors where there are externalities generated through innovative activity. Finally, under
49
50 OLS one also discovers that education in Portugal serves as a positive determinant of the
51
52 localisation of activities, suggestive of the possibility of the importance of labour market
53
54 pooling. In terms of our other, non-significant variables, one may want to note that
55
56 some of them do have the expected sign. For instance, in congruence with our
57
58
59
60

1
2
3 arguments earlier, purchase of energy products and gross investment in tangible goods
4
5 have positive coefficients.
6
7

8
9 Comparing our results with Rosenthal and Strange (2001), we unearth some common
10 features. First, the labor market pooling hypothesis, proxied by educational attainments,
11 highlights positive and significant coefficients for the US and the Portuguese case. This
12 result is also consistent with Dumais et al. (2002). Second, there is evidence that input
13 sharing favours agglomeration in the US as well as in Belgium and Portugal at high
14 aggregate spatial levels. Third, innovation, as proxied by R&D spending in the present
15 study, is shown to support the existence of knowledge spillovers for one country in our
16 sample, namely Portugal. A similar result is evidenced by Rosenthal and Strange (2001)
17 for large firms in the US case. Last, neither for the US case, nor for the three countries
18 under scrutiny in our sample there is evidence for agglomeration in sectors highlighting
19 reliance on energy resources.

30
31
32
33
34
35
36

37
38 If one assumes the relevance of our empirical specification of the determinants
39 of agglomeration despite the statistical insignificance of many of these, it may be of
40 interest to try and disentangle how much differences in agglomeration across countries is
41 driven by differences in the means of the determinants rather than their relative
42 importance across countries. A convenient method to examine this can be borrowed
43 from the labour literature due to Oaxaca (1973). Accordingly, if we consider two
44 countries i and j and the estimates of β from regressing the EG index on a number of
45 covariates using OLS for each separately, then the difference in the means of the EG
46 index, $EG_i - EG_j$, between these two countries can be decomposed into:
47
48
49
50
51
52
53
54
55
56
57
58

$$59 \quad EG_i - EG_j = (\beta_i - \beta_j)X_i + \beta_j (X_i - X_j)$$

60

1
2
3
4 where X is a vector of the means of the control variables and β is the estimated OLS
5
6 coefficient appropriately subscripted for countries i and j . The first term is the part of
7
8 the difference in means due to differences in the response of agglomeration to the
9
10 determinants measured at the mean of country i 's determinants. In contrast, the second
11
12 component serves to measure any difference in the means of the determinants across the
13
14 two countries measured at the 'returns' (i.e., for a given β) of country j .
15
16

17
18 We executed this decomposition using the OLS estimates of our specifications along
19
20 with the variable means for the three country pairs and report results in Table 9. As can
21
22 be seen, the difference in means of EG index is highest between Portugal and Ireland,
23
24 and this difference is both about equally due to higher level of mean of the determinants
25
26 as well their greater responsiveness in Portugal. In contrast, while the difference in
27
28 average agglomeration between Portugal and Belgium is nearly as high as between the
29
30 country-pair above, the factors underlying this difference are substantially different.
31
32 More precisely, while the difference in the means of the determinants acts to decrease
33
34 agglomeration relatively more in Portugal, this is counteracted by the EG index's greater
35
36 (positive) responsiveness to these. A similar pattern also emerges when one compares
37
38 the relatively similar means of agglomeration for Belgium and Ireland – while the means
39
40 of the determinants in Ireland have a greater positive influence, its level of agglomeration
41
42 is less (positively) responsive to these. It follows that, while the econometric results
43
44 presented in Table 8 appear to explain part of the agglomeration patterns observed in
45
46 each of the three countries considered separately together with existing differences in
47
48 agglomeration forces across countries, a closer, bilateral, analysis of these differences
49
50 shows that no uniform patterns emerges as to whether differences in agglomeration are
51
52 due the responsiveness of agglomeration to the determinants considered or to the
53
54 difference in levels of the determinants of agglomeration considered in Table 8.
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9
10

Finally, some remarks concerning the robustness of our results are in order. In particular, the estimated coefficients obtained in Table 8 are not always completely robust and this thus requires further clarification. First, there is the problem of data quality, in particular, our explanatory data, which stem from the Eurostat Regio database are not of an ideal quality. More precisely, as discussed in more detail in the appendix, on several occasions we needed to resort to alternative methods to fill any ‘gaps’ or otherwise would have been faced with severe sample size problems. Besides the data quality issue, there is more fundamentally the problem of whether proceeding with cross-industry regressions is the right way to capture the determinants of agglomeration. Indeed, by its very nature, there is no spatial dimension in the EG index. If, however, such factors as inputs, R&D, and energy production are very concentrated spatially and the sector under scrutiny relies heavily on these inputs, R&D, energy source, then the production should be very concentrated. In order to check this rigorously, one would then need sector-region share-regressions, rather than regressions on sector-specific EG indices. This may then explain poor results of our regressions, and on these types of regressions in general, as can be deduced from Rosenthal and Strange (2001)'s analysis.

SECTION VI: Conclusion

This paper analyses the spatial distribution of manufacturing activity and its determinants across three European countries: Belgium, Ireland, and Portugal. To our knowledge, this is the first comparative study of the location of manufacturing activities using plant level data across countries. Our analysis mainly relies on the index developed by Ellison and Glaeser (1997), which has been designed to allow for comparisons across industries and countries. Results confirm some previous findings on French, UK and US data, with traditional sectors ranking among the most agglomerated. Among the three

1
2
3 countries under scrutiny, Ireland clearly stands out with significantly different patterns of
4 spatial distribution of manufacturing activity. More precisely, despite being two
5 peripheral countries, Ireland and Portugal appear to have rather different distribution of
6 industries across space.

11

12
13 We also econometrically attempted to investigate potential determinants of the
14 observed agglomeration patterns as suggested by theoretical contributions. Our results
15 suggest, tentatively, that one may want to be careful when conducting cross-country
16 comparisons of the spatial distribution of economic activities, as there may be a lot of
17 country-specific factors that can drive the findings. More specifically, while we find
18 some evidence that backward linkages, innovative activity, and the pooling of skilled
19 labour can act to increase agglomeration, this result crucially hinges on which country is
20 being examined. When compared with the available evidence for the US, our results also
21 suggest that some industry agglomeration forces are invariant across very different
22 economies. Furthermore, while the variables mentioned above appear to explain part of
23 the agglomeration patterns observed in each of the three countries, a closer examination
24 of cross-country differences in results shows that no uniform patterns emerges as to
25 whether differences in agglomeration are due the responsiveness of agglomeration to the
26 determinants considered here or to the difference in levels of these determinants.

Appendix: Data

Belgium

Social Security data on employment

The database that has been used for the present study covers all plants established in Belgium in 1998. For each plant, we have the number of jobs, the industry it belongs to (up to five-digit classification), and the township it is located in. Employment data come from the national office for social security (ONSS), which collects employment data for all wage earners in Belgium. The notion of a plant is clearly distinguished from the employer, the latter corresponding to the notion of a firm in a general sense. If the employer has only one activity in one location, then it is considered a plant. But if the employer carries out its activity in two or more locations (branches or operation units) and/or carries out two different types of activity, each operation unit is seen as a separate plant. However, if several operation units of the same firm are located in the same township, only one plant is taken into account.

Ireland

Forfás Employment Survey

This is an annual plant level survey collected by Forfás since 1972, the policy and advisory board for industrial development in Ireland. The response rate to this survey is argued by Forfás to essentially be nearly 100 per cent, i.e., our data can be seen as including virtually the whole population of manufacturing plants in Ireland. Information at the plant level include time invariant variables such as the nationality of ownership, sector of production, and detailed regional location of each plant, as well as the level of employment in each year.

Portugal

Ministry of Employment

This is an annual plant level survey collected by the Portuguese Ministry of Employment since 1985, for all the companies operating in Portugal. It matches employers and employees and reported data include the companies' location, age, sector

of activity, sales, ownership structure and number of employees as well as worker's age, skill, occupation, tenure and schooling. A company may be a single or a group of plants, which can be at different locations. The locations, reflecting the spatial units used, take place at the municipalities (NUTS 5) and districts levels. Portugal is divided into 275 municipalities and 18 districts.

Eurostat data

Treatment of missing data

Whenever data was missing or unavailable at a given sectorial level, we extrapolated with data from the next available aggregation level. Only for R&D expenditure in Ireland, no data was available. In this case, we had recourse to national data sources – namely the *Annual Business Survey*, which is a survey of plants larger than 10 employees and covers about 80 per cent of the total population of these. Henceforth, we studentized this variable so as to make cross-country pooled regressions feasible.

Belgium:

Sectors (nacecode) with no data : 1592, 192, 193, 242, 246

Sectors with missing data : 1591 (inputs, energy, R&D exp.); 1753, 1754, 231, 232 (inv. in tang.)

Ireland:

Sectors (nacecode) with no data : 1591, 1596, 1597, 1598, 182, 191, 192, 23, 232, 246, 247, 265, 266, 271, 272, 273, 282, 2912, 334, 36, 362, 365, 366

Sectors with missing data : 154, 158, 262, 263 (inputs, inv. in tang., inv. in machines, energy); 262, 263, 364 (inputs, inv. in tang., energy)

Sectors with only zeros : 1592, 176, 231

Portugal

Sectors (nacecode) with no data : 1597

Sectors with missing data : 1592, 314 (inv. in tang., inv. in machines, R&D exp.)

Sectors with only zeros : 231

Table 1a: Average Areas

	Regional level	Local level
Belgium	43 arrondissements: 710skm	589 communes: 52skm
Ireland	27 counties: 2603skm	504 Townships: 139.4skm/ 3445 DEDs: 20.4skm
Portugal	18 distritos: 4887skm	275 concelhos: 320skm
United States	51 States: 70322skm	3141 Counties: 1142skm

Note: areas are average ones. One square kilometer corresponds to 0.3861 square miles.

Table 1b: Average Population (Density)

	Population (in 1000)		Population Density (pop/skm)
	<i>regional</i>	<i>local</i>	
Belgium	240	17.5	338
Ireland	144.5	7.5 / 1	55.5
Portugal	576	37.5	118
United States	5518	89.5	78.5

Note: figures are averages for 2002 (respectively 2000 for the US)

Table 2: Share of total manufacturing employment

	ISIC 2-digit	Belgium	Ireland	Portugal
Manufacturing of food, beverages and tobacco	31	14.19%	19.81%	10.38%
Textile, wearing apparel and leather industries	32	9.31%	7.06%	34.94%
Manufacture of wood and wood products	33	4.81%	4.83%	9.05%
Manufacture paper, paper prods., printing, publishing	34	7.64%	6.08%	5.06%
Manufacture of chemicals and chemical products	35	15.25%	13.33%	1.83%
Manufacture non-metallic mineral prods. except fuel	36	5.35%	4.58%	7.22%
Basic metal industries	37	6.37%	0.39%	1.41%
Fabricated metal products, machinery and equipment	38	30.33%	39.71%	12.04%
Other manufacturing industries	39	0.88%	2.04%	1.08%
Total		94%	98%	83%

Note: percentages only include sectors that are effectively used in the present study, so they do not sum up to 100 per cent.

Manufacture of textiles, N.E.C.	3219	-0.0114*	0.1087*	29
Sporting and athletic goods	3903	-0.026	0.0061	57
Malt liquors and malt	3133	-0.0306	-0.1542	63
Photographic and optical goods	3852	-0.0483	-0.0138	60
Tobacco manufactures	3140	-0.4349	0.3044	9

Note: results were computed for 1998; stars stand for statistical significance according to the two standard deviation rule; sectors are ranked according to the local-level E&G index ranking; *concelhos* and *distritos* correspond to the local respectively the regional geographic breakdown.

Table 7: Rank correlation of EG indices between countries

	Belgium (arrondissements)	Ireland (counties)	Portugal (distritos)
Belgium (arrondissements)	1	-	-
Ireland (counties)	0.196 (0.123)	1	-
Portugal (distritos)	0.416 (0.000)	0.057 (0.656)	1

(p-values in parenthesis)

Table 8: OLS estimations (Belgium, Ireland, Portugal)

	OLS		
	Belgium	Ireland	Portugal
	(1)	(2)	(3)
Total input purchases	0.153** (0.063)	0.046 (0.183)	1.088** (0.511)
Share of higher education	-0.154 (0.164)	-0.409 (0.461)	0.987** (0.433)
Gross inv. in tang. capital goods	5.384 (8.184)	3.269 (3.755)	9.308 (31.862)
Gross inv. in machines	-6.182 (10.156)	-6.871 (5.706)	-15.676 (31.855)
Purchase of energy products	2.547 (2.194)	4.663 (6.603)	0.305 (9.773)
R&D expenditure	7.578 (23.570)	11.923 (16.510)	134.645* (72.484)
Average plant size	-0.170 (0.194)	0.012 (0.009)	0.077 (0.116)
Constant	0.009 (0.061)	0.012 (0.194)	-0.049 (0.107)
2-digit ISIC dum.	Yes	Yes	Yes
Observations	63	55	61
Adjusted R-squared	0.24	0.03	0.25

Note : Standard errors in parentheses. ***, **, and * signify 1, 5, and 10 per cent significance levels. Data source is Eurostat. R&D expenditure is not studentized. All specifications performed using OLS estimators.

Table 9: Oaxaca Decomposition of Ellison and Glaeser index

Country i	Country j	$EG_i - EG_j$	$(\beta_i - \beta_j)X_i$	$\beta_j(X_i - X_j)$
<i>Portugal</i>	<i>Ireland</i>	0.084	0.043	0.041
<i>Portugal</i>	<i>Belgium</i>	0.078	-0.015	0.093
<i>Belgium</i>	<i>Ireland</i>	0.006	-0.010	0.016

For Peer Review Only

¹ See, for instance, Ellison and Glaeser (1997), Maurel and Sédillot (1999), Rosenthal and Strange (2001), Duranton and Overman (2005). A notable exception is Devereux et al. (2004), which deals (although with some limitations) with cross-country comparison of agglomeration patterns.

² See Barrios and Strobl (2004), Brulhart and Traeger (2005), Midelfart-Knarvik et al. (2000), Amiti (1999), among others. Some studies have also provided evidence for the existence of agglomeration economies leading to productivity gains at the city or region-level as, for example, Sveinaskas (1975) Tabuchi (1986), Moomaw (1981), Rauch (1993), Glaeser et al. (1992), Henderson et al. (1995), Ciccone and Hall (1996) and Ciccone (2002).

³ See, for instance, Puga (1998) for a theoretical analysis and Midelfart-Knarvik et al. (2000) for empirical evidence.

⁴ See, in particular, Audretsch and Feldman (1996).

⁵ See for instance, Crozet (2004).

⁶ It would be thus interesting to assess what portion of our results can be attributed to the different size and internal geographical of the countries under scrutiny. However, this is beyond the scope of this study, but will be an important topic for further research.

⁷ See for instance Openshaw and Taylor (1979) and Morphet (1997).

⁸ Note that Duranton and Overman (2002) and Marcon and Puech (2003) circumvent this issue by treating space continuously rather than using an arbitrary collection of geographical units. Although appealing, a major drawback of their distance-based localization index stems from the need of having data on the geographic coordinates for each plant, respectively zip codes of plants.

¹⁰ Final conversion tables that were used to perform a unified data set are available from the authors upon request.

¹¹ The current NUTS nomenclature subdivides the territory of the European Community into 78 NUTS1 regions, 211 NUTS2 regions and 1093 NUTS3 regions. At the local level, the NUTS4 level is defined only for the following countries: Finland, Greece, Ireland, Luxembourg, Portugal and the United Kingdom. The NUTS 5 level consists of 98433 townships or their equivalent.

¹² As an exception for Ireland we used NUTS5 (3445 spatial units) to compute the Moran index because we only had information about the contiguity matrix at this geographical level.

¹³ Descriptive statistics on the spatial units are provided in Tables 1a and 1b.

¹⁴ It should be noted that the EG index is computed at the country-level taking the overall employment distribution of common sectors as a benchmark.

¹⁵ Considering the column for Ireland in Table 2, only four sectors do highlight positive spatial autocorrelation. This result is essentially driven by our choice of spatial unit to compute the Moran index, namely DEDs rather than townships.

¹⁶ These measures concern the EG indices computed at the regional level of aggregation. When going to the local level, the same ranking is found among countries but amplitudes are smaller. Note also that the median value of the EG index for Portugal is 0.080, to be contrasted with 0.023 and 0.023 for Ireland and Belgium, as well as 0.023 for the US (Ellison and Glaeser (1997)).

¹⁷ Definition of high-tech sectors stems from Hatzichronoglou (1997). In our data base, seven hi-tech sectors are available: Drugs and medicines (3522), Spec. indus. machinery and equipment except 3823 (3824), Office, computing and accounting machinery (3825), Electrical industrial machinery and apparatus (3831), Radio, tele., communications equipment and apparatus (3832), Prof., scientific, measuring and control equipment (3851) and Photographic and optical goods (3852).

¹⁸ This latter explanation is indeed supported by Bertinelli and Decrop (2002), where it has been shown for Belgium that several high-tech sectors are ranked in the top 20 among a 237-sector classification. This result is consistent with Maurel and Sédillot (1999) and Teixeira (2002). Furthermore, note that by dropping some sectors across countries for the sake of consistency, two high-tech sectors, that were highly ranked, have been deleted for some countries: Aircraft (3845) and Watches and clocks (3853).

¹⁹ These percentages are 19, 46 and 78 respectively when considering the local level.

²⁰ Results for Italy have been made available by Giordano Mion.

²¹ Data description heavily rely on definitions provided by Eurostat (<http://epp.eurostat.ec.europa.eu/>). Further details are provided in the data appendix.

²² One should note that some of the 2-digit industry dummies were significant.
