## The relation between students' epistemological understanding of computer models and their cognitive processing on a modelling task

### Abstract

While many researchers in science education have argued that students' epistemological understanding of models and of modelling processes would influence their cognitive processing on a modelling task, there has been little direct evidence for such an effect. Therefore, this study aimed to investigate the relation between students' epistemological understanding of models and modelling and their cognitive processing (i.e. deep versus surface processing) on a modelling task. Twenty-six students, working in dyads, were observed while working on a computer-based modelling task in the domain of physics. Students' epistemological understanding was assessed on four dimensions (i.e. nature of models, purposes of models, process of modelling, and evaluation of models). Students' cognitive processes were assessed based on their verbal protocols, using a coding scheme to classify their types of reasoning. The outcomes confirmed the expected positive correlation between students' level of epistemological understanding and their deep processing ( $r = 0.40$ ,  $p = 0.04$ ), and the negative correlation between level of epistemological understanding and surface processing ( $r = -0.51$ ,  $p = 0.008$ ). From these results, we emphasise the necessity of considering epistemological understanding in research as well as in educational practice.

## Introduction

Models of scientific phenomena take a central place in [contemporary views](#) of science education (e.g. Gilbert & Boulter, Rutherford, 1998; Raghavan, Satoris, & Glaser, 1998; Schecker, 1993; Stratford, 1997; White & Frederiksen, 1998; Zaraza & Fisher, 1999). Several authors have argued that the activity of building and revising such models is particularly well suited to provide meaningful learning experiences. For instance, some emphasise the opportunity for students to think scientifically about the behaviour of complex phenomena (e.g. Bliss, 1994; Jackson, Stratford, Krajcik, & Soloway, 1996; Hestenes, 1997; Spector & Davidson, 1997; Verhoeff, Waarlo, & Boersma, 2008; Wild, 1996). Others state that if students are allowed to construct models themselves, they can not only reflect upon the science content they are supposed to learn, but also upon the nature of their own knowledge (e.g. Hogan & Thomas, 2001; Jonassen, Strobel, & Gottdenker, 2005; Spector, 2000). According to this argument, models offer students the means to externalise and to test their own mental representations of [particular](#) scientific phenomena (Coon, 1988; Doyle & Ford, 1998; Penner, 2001).

However, the benefits of engaging students in modelling activities may only be realised if students understand the nature and the purpose of models in science, as well as comprehend how models are constructed (Justi & Gilbert, 2002; Treagust, Chittleborough, & Mamiala, 2002). Such understanding may help students in using and in developing models, since it is assumed that students' epistemological understanding about models and the process of modelling is related to how they approach the material and ultimately to what they learn (Driver, Leach, Millar, & Scott, 1996; Gobert & Discenna 1997; Hammer, 1994; Schwarz & White, 2005; Van Driel & Verloop, 1999). For instance, [Crawford & Cullin \(2004\)](#) postulated that a weak epistemological understanding may act to constrain students in using and in developing scientific models. [In accordance, several authors have argued that students'](#)

1  
2  
3 epistemological understanding has an effect on their cognitive processing during modelling  
4  
5 (e.g. Hofer, 2001; Hofer & Pintrich, 1997; Schwarz, 2002a; Windschnittl & André, 1998).  
6  
7

8 Although there is ample evidence to suggest that students' epistemological understanding  
9  
10 of models and the process of modelling tends to be quite limited (e.g. Gobert, Snyder, &  
11  
12 Houghton, 2002; Grosslight, Unger, Jay, & Smith, 1991; Roth & Roychoudhury, 1994; Ryder  
13  
14 & Leach, 1999; Songer & Linn, 1991), there has been little evidence to demonstrate the direct  
15  
16 relation between students' epistemological understanding and the quality of their modelling  
17  
18 processes. If such a relationship could be confirmed, this would lend credibility to efforts  
19  
20 aimed at advancing students' epistemological understanding of models and the process of  
21  
22 modelling (e.g., Schwarz & White, 2005). The present study investigates the relationship  
23  
24 between students' level of epistemological understanding and the level of their cognitive  
25  
26 processing during computer-based scientific modelling.  
27  
28  
29  
30

### 31 32 *The epistemological status of models in science*

33  
34 The assessment of students' epistemological understanding will be based on a  
35  
36 conceptualisation of how experts perceive models and the process of modelling. Scientists  
37  
38 design models with a particular scientific purpose in mind, such as explaining, visualizing, or  
39  
40 predicting the behaviour of a scientific phenomenon (Giere, 1990; Gilbert, 1991; Gilbert, et  
41  
42 al., 1998; Justi & Gilbert, 2002; Schwartz & Lederman, 2008). Models cannot be completely  
43  
44 accurate and are almost always tentative, in the sense that they are open to further revision  
45  
46 and development (Crawford & Cullin, 2004). In addition, scientists can hold more than one  
47  
48 model for the same phenomenon depending on the context, on the purpose of the scientific  
49  
50 research and on the perspective of the scientist. An expressed model is available for other  
51  
52 scientists to discuss and to reflect upon. Therefore, scientific enterprise can be conceptualised  
53  
54 as a process of comparing and testing competing models (Giere, 1990; Hestenes, 1987; 1997;  
55  
56 Penner, 2001).  
57  
58  
59  
60

1  
2  
3 *Students' epistemological understanding of models and the process of modelling*  
4

5  
6 Grosslight et al. (1991) interviewed middle and high school science students and experts' to  
7  
8 assess their epistemological understanding of models and modelling in science. *The questions*  
9  
10 *aimed to address the following dimensions:* kinds of models, purpose of models, designing  
11  
12 and creating models, multiple models for the same phenomenon, and changing models. Three  
13  
14 general levels of understanding emerged from the interviews: Level 1, which corresponds to a  
15  
16 'naïve realist' epistemology of models and modelling, entails the notion that models are  
17  
18 simple copies of reality. Students who hold a Level 1 understanding do not make an  
19  
20 ontological distinction between the observable objects and events of the material world and  
21  
22 the entities that are created and defined for the purpose of building scientific models. *At Level*  
23  
24 *2, students do realise* that there is a specific, explicit purpose that determines the way the  
25  
26 model is constructed. These students acknowledge that the modeller makes *deliberate* choices  
27  
28 on how to achieve this purpose. According to a Level 2 understanding, *the model does not*  
29  
30 *need to reflect all properties of the real-world phenomenon being modelled.* Finally, the  
31  
32 experts held a Level 3 understanding, in that they conceived that models are constructed in  
33  
34 service of developing and testing ideas rather than replicating reality; that the modeller takes  
35  
36 an active role in constructing the model; and that models can be manipulated and subjected to  
37  
38 tests in the service of informing ideas and generating predictions. *The main characteristic to*  
39  
40 *distinguish Level 2 from Level 3 is* that the main focus of a Level 2 conception is still on the  
41  
42 model and the reality modelled and not on the ideas portrayed.  
43  
44  
45  
46  
47  
48  
49

50  
51 Employing this characterisation, Grosslight et al. (1991) found that the majority (67%) of  
52  
53 middle school students were at level 1, 12% were at level 2, and 18% reached an  
54  
55 understanding that fell in between the levels 1 and 2 (i.e. mixed level). Of the high school  
56  
57 students, only 23% had level 1 scores and the rest were split evenly between the mixed level  
58  
59  
60

1  
2  
3 1/2 (36%) and level 2 (36%). None of the students in Grosslight et al.'s (1991) study reached  
4  
5 Level 3.  
6

7  
8 The general trend in these findings has been confirmed in several other studies (cf.,  
9  
10 Lederman, 1992). For instance, Treagust et al. (2002) found that a great deal of secondary  
11  
12 science students did not understand how models are used in the development of scientific  
13  
14 ideas. Most students valued the visual aspect of scientific models, but were not able to reason  
15  
16 beyond the descriptive nature of models (cf. Barowy & Roberts, 1999). However, counter to  
17  
18 the findings from Grosslight et al.'s study (1991), Treagust et al. (2002) found that students,  
19  
20 in general, do have an understanding that it is possible to have multiple models for the same  
21  
22 phenomenon and that each model displays a particular perspective or emphasis. Schwarz &  
23  
24 White (2005) found that students' epistemological understanding regarding the creation,  
25  
26 evaluation and revision of models was moderate (cf. Spitulnik, Krajcik, & Soloway, 1999).  
27  
28 This was still the case after students had worked through a curriculum in which they learned  
29  
30 about the nature of scientific models and engaged in modelling activities. When they were  
31  
32 asked about the relative value of alternative models, for instance, students responded that all  
33  
34 models are of equal value. In addition, more than half of the students agreed that model  
35  
36 revision occurs when there is new information or evidence available, or when the model is  
37  
38 simply wrong.  
39  
40  
41  
42  
43  
44

45  
46 However, the approach taken by Grosslight et al. (1991) focuses on an epistemology of  
47  
48 science at a rather abstract level. The validity of this approach has been questioned, because  
49  
50 students epistemological ideas are likely to be context-bound (e.g. Elby & Hammer, 2001;  
51  
52 Hofer & Pintrich, 1997; Hogan, 2000; Paulsen & Wells, 1998). As a consequence, in specific  
53  
54 contexts, students may entertain advanced epistemologies without being able to articulate the  
55  
56 underlying viewpoints in general. Moreover, a student could provide 'high-level' answers on  
57  
58 a generic questionnaire, based on hearsay only. Finally, different contexts make different  
59  
60

1  
2  
3 demands upon students, and some forms of epistemological understanding may be more  
4  
5 beneficial to learning in some contexts than in others (Elby & Hammer, 2001; Hogan, 1998;  
6  
7 Leach, Millar, Ryder, & Séré, 2000; Schwarz, 2002b). Therefore, while maintaining the  
8  
9 dimensions and levels as defined by Grosslight et al. (1991), a more legitimate assessment  
10  
11 could be achieved if the questions are situated in the concrete problem context at hand.  
12  
13

14  
15 *Studies relating students' epistemological understanding of models and the process of*  
16  
17 *modelling with their cognitive processing*  
18  
19

20  
21 Although many of the studies cited above, conclude suggesting that students' poor  
22  
23 epistemological understanding might restrict their cognitive processing during modelling,  
24  
25 there is little direct evidence for such a relation. Several authors have provided evidence for a  
26  
27 relation between students' epistemological understanding and their performance on general  
28  
29 inquiry activities (e.g. Buffler, Allie, Lubben, & Campbell, 2001; Gomes, Borges, & Justi,  
30  
31 2008; Hammer, 1994; Millar, Lubben, Gott, & Duggan, 1994; Purdie, Hattie, & Douglas,  
32  
33 1996; Ryder & Leach, 1999; Schauble, Glaser, Raghavan, & Reiner, 1991; Schommer, 1990;  
34  
35 Songer & Linn, 1991). However, as argued above, such findings cannot straightforwardly be  
36  
37 generalised across contexts.  
38  
39  
40

41  
42 Within the field of scientific modelling, there have been only a few studies that attempted  
43  
44 to relate students' epistemological understanding to their cognitive processing during  
45  
46 modelling. First, Schwarz & White (2005) evaluated a model-centred method to science  
47  
48 education, where they taught middle school students on the nature of scientific models and in  
49  
50 which students were engaged in the process of modelling. Based on correlational results,  
51  
52 including significant correlations between pre-test epistemology scores and post-test scores on  
53  
54 an applied physics test, Schwarz & White (2005) conclude that a better epistemological  
55  
56 understanding may significantly contribute to the acquisition of modelling skills and physics  
57  
58 knowledge. Correspondingly, Gobert & Discenna (1997) found that students who hold a  
59  
60

1  
2  
3 sophisticated epistemology of models were able to make significantly more inferences on the  
4 basis of their models compared to those who hold a naïve epistemological understanding.  
5  
6  
7  
8 However, both studies were focused at learning outcomes and did not directly observe the  
9  
10 students' cognitive processes during their modelling task.  
11

12  
13 Talsma (2000) took another approach, by inferring students' epistemological and strategic  
14 understanding (i.e. understanding of students related to how they define, plan, implement and  
15 evaluate modelling activities) from the notes they had taken during the construction of  
16  
17 computer models in the domain of ecosystems. She found that most students constructed  
18  
19 models with a specific purpose focused on reality (i.e. Level 2). In evaluating their models,  
20  
21 students generally commented that they would add more variables, reflecting an  
22  
23 epistemological understanding that is characterised by the addition of new information (i.e.  
24  
25 Level 2). Only few students showed a focus on ideas or the testing of possible theories (i.e.  
26  
27 Level 3). Regarding students' strategic understanding, Talsma (2000) found that many  
28  
29 students were sufficiently able to define the phenomenon to be addressed by their models. In  
30  
31 addition, all students constructed models that could be executed on the computer, but often  
32  
33 included redundant relations and variables. However, given that Talsma (2000) inferred  
34  
35 students' strategic and epistemological understandings from their modelling processes, this  
36  
37 approach is not suitable to test the relation between understanding to process. In fact, none of  
38  
39 the above-mentioned studies focused on whether and how students' epistemological  
40  
41 understanding is related to their cognitive processing during modelling.  
42  
43  
44  
45  
46  
47  
48  
49

50  
51 To perform well on an complex and open task, like a computer modelling task, students  
52  
53 need to engage in Deep cognitive processing, as described in the work of Marton & Säljö  
54  
55 (1976; 1997), Ramsden (1992), and Entwistle (1981; 1988; 2001), involves active learning  
56  
57 processes, such as relating ideas, looking for patterns and principles and attempting to  
58  
59 integrate new information with prior knowledge and experience. Surface cognitive  
60

1  
2  
3 processing, in contrast, entails processes without much reflecting and involves treating the  
4 learning material as more or less unrelated bits of information. Surface processing does not  
5 imply elaboration of the learning material and leads to more restricted learning processes.  
6  
7 Accordingly, it can be expected that high scores on epistemological understanding may be  
8 related to the employment of more deep processes and fewer surface processes (cf. Kardash &  
9 Howell, 2000; Windschnitl & André, 1998).

### 17 *The current study*

18  
19 The central aim of the present study is to investigate the relation between students' cognitive  
20 processing during a modelling task and their epistemological understanding of the task at  
21 hand. In particular, we expect that a more sophisticated epistemology of models and  
22 modelling will be associated with more deep cognitive processes and less surface cognitive  
23 processes during modelling. Therefore, our main research question is:

24  
25 What is the relation between the level of students' epistemological understanding of  
26 models and the process of modelling and the level of their cognitive processing during  
27 modelling?

## 38 **Method**

### 39 *Participants*

40  
41  
42 The study involved twenty-six students from eleventh-grade pre-university education, with a  
43 major in science. Their science teachers had confirmed that the students had no prior  
44 experience with dynamic modelling or the domain of mechanics. Students' age ranged  
45 between 16-18 years. During the modelling task, participants worked in pairs, which were  
46 composed by having the students choose their own partners from within a group of familiar  
47 students.  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

### *Modelling task*

Participants were presented with a task to explore and extend a model of the distance covered by an ice-skater<sup>1</sup>. Since participants had no prior experience with modelling, a completely open modelling task would be too complex for them to be successful within the time constraints of the experiment. Therefore, participants were given an incomplete model as a starting point. Such a model revision task enables the novice modeller to concentrate on trying to comprehend and improve a model without having to start from scratch.

The modelling task was implemented in Powersim® constructor Lite version 2.51, which is freely available for non-commercial use in educational settings (Byrknes & Myrtveit, 1997). Powersim is a modelling tool based on system dynamics (see Figure 1). Powersim models are built of the five system dynamics model building blocks: Stocks, rates, auxiliaries, constants, and connectors. Stocks represent a quantity that can increase or decrease from some starting value. A rate connected to a stock decides how quickly the quantity in the stock will change. Quantities can be represented either as constants (i.e. fixed values), or as auxiliaries (i.e. calculated from other quantities). Finally, connectors indicate dependencies between model elements. To insert a modelling element, students can drag and drop the icons on the screen they think are relevant for the phenomenon being modelled, creating a qualitative diagram of the phenomenon. While creating this diagram, students can quantify these elements by entering values and formulas. Once the model has been quantified it can be run. When students run their model, Powersim automatically generates the differential equations required to perform calculations. The results of simulations runs over time can be displayed as graphs or tables.

<sup>1</sup> Adapted from 'Computerondersteund modelleren natuurkunde: Een sportieve beweging' ['Computer-supported modelling physics: good sports in motion'] (courtesy of Koos Kortland, Kees Hooyma, and Development Group Dynamic Modelling, University of Utrecht). Available from: <http://www.cdbeta.uu.nl/vo/onderwijsmateriaal.php?id=10>

[Insert figure 1 about here]

The modelling task was presented in a cover story in which a scientist attempted to construct a model of this phenomenon. Participants were provided with measurements that were obtained by the scientist, which they could use to test the model. The empirical data was presented in two graphs, one for the distance covered by the skater (see upper right hand side of Figure 1) and one graph for the velocity of the skater (lower right-hand side of Figure 1). Participants' task was to extend their model in such a way in that it would provide a good match with the data. Successful completion of the task would require the identification of two friction forces and of a feedback loop which runs from velocity to air resistance. This feedback implies that a skater at a higher velocity experiences more air friction, which consequently leads to a more rapid decrease in velocity.

## Data collection

### *Level of epistemological understanding*

An open-ended questionnaire was developed to measure students epistemological understanding of the nature of models, the purpose of models, the design and revision of models, and the evaluation of models. The questionnaire (see Appendix A) was patterned after the work of Grosslight et al. (1991). *The questionnaire was presented directly after the modelling task, which served as a context to frame the questions.* Answers of students to the items in our questionnaire were first analysed qualitatively to examine whether they would fit in one of the four following *dimensions*:

1. Nature of models: How to define a model?
2. Purposes of models: What is the purpose of a model and modelling?
3. Design and revision of models: How are models constructed and when and how are they revised?

- 1  
2  
3 4. Evaluation of models: How are models evaluated and what are the criteria for the  
4  
5 evaluation of a model?  
6  
7

8 The answers of every individual student were first interpreted in terms of the **dimensions**  
9 mentioned above. Next, it was investigated within every **dimension** whether the provided  
10 answers could be categorised according to level of sophistication. Each student was given a  
11 level of epistemological understanding rating (high, moderate, low) for each of the four  
12 **dimensions**, employing the three levels articulated in the studies of Carey & Smith (1993) and  
13 Grosslight et al. (1991; see Appendix B for scoring and examples). Two independent judges  
14 each scored half of the data. Interrater reliability was considered to be acceptable for the  
15 present purposes ( $n = 52$ , Cohen's kappa = 0.70) (Heuvelmans & Sanders, 1993).  
16  
17

#### 18 *Cognitive processing*

19  
20 Throughout the modelling task, both students' onscreen actions as well as the verbal  
21 communication between them were recorded using the program Lotus ScreenCam™. Verbal  
22 protocols were obtained by transcribing these recordings. Students' cognitive processing was  
23 measured by analyzing these transcripts employing the protocol analysis scheme of Sins et al.  
24 (2005). Although students' verbalizations and behaviours do not fully reveal their covert  
25 cognitive processes, the assumption of the present methodology is that the nature of students'  
26 discourse and of their actions affords valid indications of the level of their cognitive  
27 processing (cf. Hogan & Thomas, 2001). The transcripts were scored employing two scoring  
28 rubrics that were taken from the scheme of Sins et al. (2005)<sup>2</sup>: a) students' reasoning  
29 processes during modelling and b) type of reference made by students during reasoning (see  
30 Appendix B for coding scheme).

54  
55  
56  
57

---

58 <sup>2</sup> In addition to these two categories, the protocol analysis scheme of Sins et al. (2005) also includes the  
59 category: 'topic focus of students' reasoning'. We did not include this code in the present analyses, since  
60 reasoning processes coupled with the type of reference students make during process-episodes provide sufficient  
information concerning students' level of cognitive processing.

Reasoning processes such as analysing or explaining mostly involve several turns by both partners in a dyad (Brickell, Ferry, & Harper, 2002). Therefore, the unit of analysis was determined to be at the episode level, an episode being defined as a period of coherent continuous talk on a single issue. Episodes were segmented on the basis of following non-content criteria (cf. Chi, 1997). A new episode would start:

- Following each run of the students' model.
- Following each interval of more than 15 s during which nothing is said.
- At the start and at the end of each experimenter intervention.
- The maximum length for a segment is 1 min. If a segment lasts longer, the segment will be more closely analysed in order to see whether segmentation is possible on the basis of changes in reasoning process or changes in focus (often signalled by words as: "Okay ..." or "Now ....").

Reasoning episodes in which students are elaborating on the modelling task and connect to their knowledge, which can be either gained from the task at hand or prior knowledge, were designated as deep cognitive processing. Episodes in which students posit unelaborated statements without reference to available knowledge were labelled as surface cognitive processing. The remaining episodes were scored indifferent, and excluded for the purpose of this analysis. The following specific codes were operationalised as indications of deep processing:

- Evaluating with reference to knowledge
- Explaining with reference to knowledge
- Quantifying with reference to knowledge
- Inductive reasoning with reference to knowledge
- Analyzing with reference to knowledge

The following codes indicated surface processing:

- 1
- 2
- 3
- 4 – Evaluating with no reference to knowledge
- 5
- 6 – Quantifying with no reference to knowledge
- 7
- 8 – Analyzing with no reference knowledge
- 9

10  
11 Since the relation between epistemological understanding and cognitive processing was  
12 scored at the individual level, while students' cognitive processing had to be assessed in a  
13 collaborative setting, we counted the numbers of utterances that individual students  
14 contributed to the different types of process episodes as an indicator of individual processing.  
15 Because the total numbers of utterances differ across individuals, reporting frequencies would  
16 result in a skewed image. Therefore, for each individual student within a dyad, the amounts of  
17 deep and surface processes were expressed as proportion of total number of utterances by that  
18 student.  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29

30 Interrater reliability for these codes was determined by comparing the ratings of two  
31 independent judges ( $n = 212$ ; Cohen's kappa = 0.75). This interrater reliability can be  
32 regarded as satisfactory for the present purposes (Heuvelmans & Sanders, 1993).  
33  
34  
35  
36

### 37 *Procedure*

38  
39  
40 In order to get acquainted with system dynamics modelling in Powersim, each student  
41 individually worked through a tutorial<sup>3</sup>. In this tutorial, students were presented with an  
42 example model of a water tank. This system provides a very simple example to illustrate  
43 fundamental aspects of modelling and the behaviour of dynamic systems is that of a water  
44 tank containing a faucet and a drain. The volume of water in the water tank is represented by  
45 the stock variable (i.e. reservoir variable), and the flows represent respectively the inflow of  
46 water into the water tank through the faucet and the outflow of water from the water tank  
47 through a sink. The water tank model, its elements (i.e. variables and relationships between  
48

<sup>3</sup>Adapted from: Computerondersteund modelleren: Basishandleiding Powersim [Computer supported modelling: Powersim manual (in Dutch) available from: <http://www.cdbeta.uu.nl/vo/onderwijsmateriaal.php?id=17>

1  
2  
3 variables) and how it can be built in Powersim were explained to students in the instruction.  
4  
5 Also, students could execute and revise parts of the water tank model in the Powersim  
6  
7 environment. The instruction took about one hour. Subsequently, participants were grouped in  
8  
9 dyads. Participants were informed that they were going to explore and subsequently revise  
10  
11 models working in couples. Next, dyads read the modelling task and were presented with the  
12  
13 initial model version and with the data. Dyads were asked to collaboratively revise the model  
14  
15 for approximately one and a half hour. Finally, students completed the epistemology  
16  
17 questionnaire.  
18  
19  
20  
21

## 22 **Results**

### 23 *Cognitive processing*

24  
25 Table 1 shows the mean percentages with examples of the deep and surface cognitive  
26  
27 processes students employed during modelling. It becomes apparent from Table 1 that, on  
28  
29 average, the students employed much more surface processes compared to deep processes.  
30  
31 Most surface processes involve students' quantifying their model without referring to  
32  
33 knowledge, whereas for deep processes, the process that is employed the most is students'  
34  
35 quantifying with reference to knowledge. The processes explaining with reference to  
36  
37 knowledge and analyzing with reference to knowledge, occur only rarely (see Table 1).  
38  
39  
40  
41  
42  
43  
44  
45

46 [Insert Table 1 about here]

### 47 *Level of epistemological understanding*

48  
49 Based on their answers on the questionnaire, students got graded as Level 1, 2 or 3 on each of  
50  
51 the four dimensions of epistemological understanding. As shown in Table 2, on three of the  
52  
53 four dimensions more than half of the students reached a Level 2 epistemological  
54  
55 understanding. On the dimension Purposes of models 46% of the students reached Level 2  
56  
57 and 42% of the students reached a Level 3 epistemological understanding. Internal  
58  
59  
60

1  
2  
3 consistency for epistemological understanding on these four categories showed to be  
4  
5 acceptable ( $\alpha = 0.70$ ). Consequently, a students' epistemological understanding of models and  
6  
7 modelling could be expressed in a single score as the mean of four subscores. Over the whole  
8  
9 sample of students, the mean score was 2.07 with a standard deviation of 0.41.  
10  
11

12  
13  
14 [Insert table 2 about here]

15  
16  
17 *Relation between epistemological understanding and cognitive processing*

18  
19 To investigate the extent to which students' epistemological understanding of models and  
20  
21 modelling is related to their level of processing, we computed the correlation between both  
22  
23 measures, using the non-parametric Spearman rank method. Both the correlations between  
24  
25 epistemological understanding and deep processing ( $r = 0.40$ ,  $p = 0.04$ ) and between  
26  
27 epistemological understanding and surface processing ( $r = -0.51$ ,  $p = 0.008$ ) were significant  
28  
29 and in the expected directions. Figures 2 and 3 provide the respective scatter plots.  
30  
31  
32

33  
34  
35 [Insert figure 2 about here]

36  
37  
38 [Insert figure 3 about here]

39  
40  
41 To corroborate the quantitative results presented above, we provide an exploratory qualitative  
42  
43 analysis of the relationship between students' answers on the epistemology questionnaire,  
44  
45 and their reasoning during modelling.  
46  
47

48  
49 First, we will consider Roel, who expressed a preference for simple models:

50  
51  
52 'By using very simple models, you may use them for multiple purposes'

53  
54  
55 (Roel; Epistemology score: Level 3, Process of modelling)  
56  
57  
58  
59  
60

1  
2  
3 While working on the modelling task, together with Dave, Roel acted in accordance with this  
4  
5 view when they were reasoning about how to quantify a feedback loop they had just  
6  
7 implemented in their model, making “air friction” dependent on “velocity”:  
8  
9

10  
11 R The formula for deceleration should be: velocity multiplied by air  
12  
13 friction, which should actually be squared  
14

15  
16 R Actually we could implement that later in our model, but we have to  
17  
18 start simple  
19

20  
21 R Also, we should also take the air density coefficient into  
22  
23 consideration  
24

25  
26 D Yes  
27

28  
29 R But we will do that later  
30

31  
32 (Protocol: Dave and Roel; Process code: Quantify and reference to knowledge)

33  
34 In this excerpt, Roel correctly identifies the quadratic relation between the “air friction” and  
35  
36 “velocity”, but nevertheless prefers to start with a simpler formula, in order to keep his model  
37  
38 simple from the start.  
39

40  
41 Next, we will consider Mark, who defined a model as:

42  
43 ‘A model approaches reality by means of several assumptions and calculations. A  
44  
45 model is built based on various relations, which are either known or estimated. These  
46  
47 are entered in the computer in this case, after which these quantitative relations can be  
48  
49 investigated and assumptions tested’  
50

51  
52 (Mark; Epistemology score: Level 3, Nature of models)  
53  
54

55  
56 This high level epistemological stance on the nature of models is reflected in Mark’s  
57  
58 contributions while working with Hugo to quantify variables in their model:  
59

60  
M So we have to multiply air friction and velocity, velocity should be

1  
2  
3 squared, and frontal surface of the skater  
4

5 M But those are all things we have to estimate, we do not have any data  
6  
7 for this  
8  
9

10 M It is difficult to estimate these, since they are all constants actually  
11

12 H What do you think that the frontal surface of the skater could be?  
13

14 M We cannot look it up somewhere  
15

16  
17 (Protocol: Mark and Hugo; Process code: Quantify and reference to knowledge)  
18

19  
20 In agreement with his view that models are based on assumptions of the modeller, Mark  
21 asserts that, if values for variables are not known, they can be estimated based on their prior  
22 understanding.  
23  
24

25  
26 More generally, in the protocols of students with a high epistemological understanding,  
27 there is frequent reference to knowledge. This indicates that students consider their own  
28 understanding as contributing to the advancement of their model. This is exemplified in the  
29 following excerpt taken from the protocol of Dave and Roel:  
30  
31  
32  
33  
34

35  
36  
37 R The skater does not skate at a constant velocity, it changes over time  
38

39 R He starts at 15 meters per second I think and that is...  
40

41  
42 D No, but it figures, he stops at a moment, he stops skating and then he  
43 slides on and then he goes this fast  
44  
45

46 D At the beginning he decelerates rapidly and then the deceleration  
47 becomes less, you see?  
48  
49

50 R Yes, so the friction is higher at the start and becoming less at the end  
51  
52

53 (Protocol: Dave and Roel; Process code: Reason and reference to knowledge)  
54

55  
56 By contrast, students who scored low on epistemological understanding tended to focus on the  
57 visual aspects of models. As an example consider the way Marije defined a model:  
58  
59  
60

1

39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

‘[A model is a] scheme where you can change things and where you can see what the output is if you add or change something’

(Marije; Epistemology score: Level 1, Nature of models)

Fully in line with this stance, Marije and her partner Lola focused on visual attributes of their model:

L Maybe we have to enter a circle here

M A circle from velocity and...

L I really do not understand this

M But you know, distance is also dependent on deceleration and velocity, otherwise there would be no arrows going to that variable

(Protocol: Marije and Lola; Process code: Analyse and no reference to knowledge)

Denise and Astrid expressed the following epistemological views on respectively the purpose of models and on the process of modelling:

‘Models are a collection of measurements’

(Denise; Epistemology score: Level 1, Purpose of modelling)

‘Modelling = playing with values and formulas on the computer of the model matches the measured values’

(Astrid; Epistemology score: Level 2, Process of modelling)

Both views are reflected in the way Denise and Astrid go ahead to evaluate the fit between the empirical data and the output generated by their model:

1 D Yes he {the model graph} should be somewhat

2 D Yes, the graph is going too far, right?

3 A Yes, but that does not matter that much now

4 D No, we have to make the graph better here

- 1  
2  
3 5 A These values we entered are just too low  
4  
5  
6 6 D Why do we not just change the data?  
7  
8 7 D Look, here he {the graph} is just too low, but here it looks  
9  
10 fine  
11  
12 8 A It is just manipulating with numbers!  
13  
14

15 (Protocol: Denise and Astrid; Process code: Evaluate and no reference to knowledge)  
16

17  
18 In this episode both of the epistemological views presented above are enacted: whereas  
19  
20 Denise focuses on the graph in lines 1, 2, 4 and 7 and even conflates empirical data with  
21  
22 model output in line 6, is Astrid engaged in fitting the model with the data as exemplified in  
23  
24 line 8.  
25

26  
27 Overall, students scoring low on epistemological understanding employed mainly surface  
28  
29 processes in which reasoning was restricted to the model at hand instead of being focused on  
30  
31 attempting to comprehend the phenomenon modelled.  
32  
33

### 34 35 **Conclusion and Discussion** 36

37  
38 The purpose of the present study was to investigate the relationship between the students'  
39  
40 cognitive processing during computer modelling (i.e. deep versus surface processing), and  
41  
42 their epistemological understanding. The assessment of epistemological understanding was  
43  
44 framed within the task at hand, because students' epistemologies are supposed to be context-  
45  
46 bound. We expected that students with a more sophisticated epistemological understanding  
47  
48 would engage more in deep processing, whereas students with a poor epistemological  
49  
50 understanding would mainly stick to surface processing.  
51  
52

53  
54 Findings indicate that, on average, students' epistemological understanding of computer  
55  
56 models and the process of modelling was about Level 2. In comparison to studies with similar  
57  
58 students reported in the literature, the students in our sample seem to hold relatively advanced  
59  
60 epistemological viewpoints. An explanation for this finding may be come from the assessment

1  
2  
3 being framed in the context of a more or less authentic computer modelling task. By contrast,  
4  
5 in the work of both Grosslight et al. (1991) and Treagust et al. (2002) students'  
6  
7 epistemological understanding was assessed within the context of a general science  
8  
9 curriculum. In Schwarz' and White's (2005) study, there was the context of a concrete  
10  
11 modelling task, but this task was highly constrained, in the sense that students were asked to  
12  
13 chose among three (or four) computer-modelling rules the one that most closely resembled  
14  
15 their own mental model.  
16  
17

18  
19  
20 With respect to the relation between the students' epistemological understanding of  
21  
22 models and the process of modelling and their cognitive processing, we found significant and  
23  
24 substantial correlations between epistemological understanding and deep processing  
25  
26 (positive), and between epistemological understanding and surface processes (negative).  
27  
28

29  
30 Exploratory qualitative analysis of protocols of the groups scoring low versus high on  
31  
32 epistemological understanding corroborated the quantitative analyses, in that students'  
33  
34 epistemological stances were enacted in their reasoning. For instance, the finding that students  
35  
36 who are high on epistemology refer to prior knowledge during modelling seemed to be related  
37  
38 to the epistemological stance that one's own understanding of the phenomenon is useful in  
39  
40 constructing the model. This may indicate that these students conceptualized a model as an  
41  
42 idea portrayed, and that in order to improve their model it needs elaborate thinking based on  
43  
44 their own understanding. Students expressing poor epistemological understanding of models,  
45  
46 in contrast, resorted to mainly employing surface processes in which they focused on visual  
47  
48 aspects of their model, were engaged in model fitting behaviour and even confused model  
49  
50 output with empirical data. The protocols of these students reflected an epistemological stance  
51  
52 which regards models as the reality being portrayed, instead of as tools to comprehend the  
53  
54 phenomenon modelled.  
55  
56  
57  
58  
59  
60

1  
2  
3 As a limitation of the study, it should first be noted that students' epistemological  
4 understanding was assessed after the task, in order to get a more valid and contextualised  
5 portrayal of their ideas. The obvious disadvantage would be that the students might have  
6 changed their epistemological understanding as a consequence of working on the task, and  
7 that the causal direction of the relation we found could be either way. However, as we had no  
8 specific epistemological instruction, and as the duration of the task was quite limited, we  
9 regard it more likely that students' epistemological understanding affected their processing,  
10 than the other way round. In a follow up study the assessment of epistemological  
11 understanding could precede the assessment of cognitive processing, if we would introduce an  
12 extra modelling task preceding the current one, to provide a proper context for the  
13 epistemology assessment.  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28

29 Moreover, students' epistemological understanding was assessed in an individual setting,  
30 while cognitive processing was assessed in a collaborative setting, were students had selected  
31 their own partners. In this self-selected collaborative setting, a students' contributions will  
32 also be influenced by their partner's contributions. Nevertheless, students' contributions to  
33 either deep or surface process episodes provide insight in their abilities (cf. Hogan, 1999;  
34 Hogan & Thomas, 2001). For instance, students who are more capable to elaborate upon their  
35 model compared to their partners, are also likely to contribute more to process-episodes that  
36 are scored as deep. In this study, the focus was on the relation between individual  
37 understanding and individual performance, and working in dyads was the way to elicit the  
38 cognitive processes we were interested in. It has been documented that the composition of  
39 dyads in terms of equal ability versus mixed ability learners may lead to differential learning  
40 effects (e.g. Gijlers & de Jong, 2005; Webb, 1991; Webb, Welner, & Zuniga, 2001). From an  
41 educational perspective, it would be worthwhile to investigate whether similar effects occur if  
42 partners vary with respect to their epistemological understanding.

## Appendix A

In the next statements we ask you for your view on models and modelling (for example the modelling of friction forces). At every statement you have to indicate whether you agree or disagree with this statement and provide also a short explanation of why you agree or disagree. At some points, you will be presented with an open question, try to provide a clear answer.

1. How do you define a model?

Try to mention everything you can think of when you hear the words 'model' and 'modelling'. Use whole sentences in your answer.

2. Why are models used in science?

3. The model of the scientist in the assignment is wrong

Agree/ Disagree, because:

4. Only a small part of reality can be described with this model

Agree/ Disagree, because:

5. How do you decide if a model is correct?

6. Scientist should test their model(s)

Agree/ Disagree, because:

7. It is impossible to decide which model is the best

Agree/ Disagree, because:

8. The scientist in the assignment has to perform more measurements/ more experiments in order to construct a better model

Agree/ Disagree, because:

1  
2  
3 9. Another scientist (Dr. Schintaler) thinks there is no way to decide which model can  
4 describe the given data the best. What do you think?  
5  
6

7  
8  
9 10. Models are useful in order to better understand phenomena in physics (for example,  
10 friction forces or resonance)  
11

12 Agree/ Disagree, because:

## Appendix B

### Scoring of students' epistemological understanding of models and the process of modelling

#### 1. Nature of models

Level	Description	Examples
1.	Students view a model as a creation of an object on the basis of data	'A model is created by means of the data you have measured'
	Students view a model as a (vague) scheme, concept map or drawing of variables. Students focus on visual aspects of models	'[A model is] an overview of a situation where a lot of things influence other things' '[A model is a] scheme where you can change things and where you can see what the output is if you add or change something'
2.	Students view a model as a (simplistic) representation of reality. Students acknowledge that a model represents something else (i.e. reality)	'With a model you can represent reality' 'A model is a simplified representation of reality in which you can make estimates'
	Students view a model as a simulation (i.e. representation of reality), formula, or as a computational tool. The concern is with how the model works.	'[A model is] a simulation of reality' 'You can simulate different things, such as kinetics, heating of objects, etc.' 'A model is an extended formula with which you can predict measurements' 'By employing several variables and formulas, we can build a simulation of a particular situation or event'
3.	Students acknowledge that a model draws on assumptions, is a theory of reality. Students view a model as a depiction of an idea of a researcher.	'A model is an image of reality, measurements can be explained with a model [...] everything is set up from a theoretical and fundamental (and simplistic) basis'

#### 2. Purposes of models

Level	Description	Examples
1.	Students think models are used to measure things, find out answers, collect data (students conflate data with model output)	'[A model is used] to simulate, so that you no longer have to measure things' 'In science models are used to better notice and discover things'
2.	Students view models to be of use for showing how something works (i.e. provide an overview of a phenomenon) or to show dependencies between variables	'Models are used to gain a better insight into difficult and complex issues' A model quickly provides relationships between different variables'

Students think models are useful to make research more efficient or to analyse data

'[Models are used] to conduct efficient research. You can easily add relationships and change variables'

'Models can be used for the analysis of measurements'

3. Students think models are useful for making predictions about a phenomenon (in service of improving the design of an artefact)

'[Models are used to] make predictions of particular scientific processes'

'[Models are used to] make predictions of what happens when you change something in the design of an object/ apparatus'

### 3. Process of Modelling

Level	Description	Examples
1.	Students view model construction/ revision simply as building/ revising a model	'From a situation you make a model' 'Modelling is to construct and change a model'
2.	Students define model revision as model-fitting	'Modelling = playing with values and formulas until the output of the model matches the measured values' '[Modelling is] changing values and formulas on the computer with more accurateness'
	Students view model construction/ revision as changing or adding variables or relations to a model	'[Modelling is] deciding which factors are involved' 'Modelling is when you add several important factors to predict something'
	Students view modelling as a process of specifying variables (and monitoring the output of their model)	'[Modelling is] putting formulas together, by which you enable more factors to play a role in the output' '[Modelling is] examining what the effect is of changing a variable'
	Students view modelling as a process of simulating a phenomenon	'[Modelling is] to simulate a scientific phenomena'
3.	Students try to keep their model as simple as possible in order to obtain more predictive validity (i.e. simplistic elegance in constructing a model)	'By using very simple models, you may use them for multiple goals'
	Students think that model revision occurs by rethinking one's data and their implication as well as the purpose of the models	'If the researcher uses new measurement methods, he may come to other conclusions regarding his/ her model and may ultimately change his/ here model'

#### 4. Evaluation of models

Level	Description	Examples
1.	Students report that they vaguely check their model (at face value or compare the model with reality)	'If the model is build logically and based upon controllable facts' 'If the model is reliable'
2.	Students think that models are evaluated by comparing it with empirical data	'If it matches the measurements' 'You have to compare the data from the model with data you have obtained and the one that fits the best is correct'
	Students view model evaluation as examining whether all relevant variables are included in the model	'Checking whether you have taken all factors into account'
3.	Students report that they evaluate models by comparing it with data obtained from multiple measurements or with the opinion of other researchers	'You have to ask other scientists for their opinion'

## Appendix C

### Coding scheme for modelling processes

---

#### Type of reasoning process

---

<u>Evaluate</u>	Students positively/ negatively evaluate an element(s) in relation to their model. Students make a (elaborate) value judgment on a modelling element
<u>Explain</u>	Students explain to each other how elements within their model work or why they were included, etc. An explanation must be preceded by a clear-cut question of one of the students
<u>Quantify</u>	Students talk about quantifying or specifying a quantity or relation within their model
<u>Inductive Reasoning</u>	Students elaborate upon/ about elements within or with respect to their model (involves mainly qualitative reasoning)
<u>Analyse</u>	Students talk about/ interpret modelling elements without further elaboration. Or identify factors that may be relevant/ included in their model without further elaboration (i.e. factors are uttered by the students without further discussion)

---

#### Other processes

---

<u>Read</u>	Students read or paraphrase
<u>Off task (no further coding)</u>	Students talk about subjects unrelated to the modelling task

---

---

#### Type of reference

---

<u>None</u>	No reference to model components or knowledge
<u>Physics knowledge</u>	Use of terminology, concepts (i.e. units, quantities), formula's common in physics
<u>Mathematics knowledge</u>	Use of terminology, concepts, formula's common in mathematics
<u>Experiential knowledge</u>	Knowledge from everyday experience

---

Table 1.

Mean percentages (with standard deviations in parentheses) and examples of process episodes (i.e. deep versus surface cognitive processes)

Students' cognitive processing	Examples	Mean (SD)
<b>Deep processing</b>		
Evaluate with reference to knowledge	'The change of velocity is a particular deceleration that disappears [in the model], that is correct'	1.68(2.41)
Explain with reference to knowledge	'Look, the velocity, look, the harder you go, the more the deceleration you experience, so the velocity slows down, so the deceleration also becomes less'	0.22(0.46)
Quantify with reference to knowledge	'The larger the velocity, the larger the air friction, so therefore we have to multiply [these variables]'	7.09(6.69)
Inductive reasoning with reference to knowledge	'Air friction depends on your velocity, if you go faster then your air friction is higher'	5.13(4.33)
Analyse with reference to knowledge	'We have to include air resistance in the model, because that is a relevant variable for the ice skater assignment, right?'	0.97(1.10)
<b>Surface processing</b>		
Evaluate with no reference to knowledge	'This [the graph] is almost correct, look it runs through all [data] points'	6.02(3.17)
Quantify with no reference to knowledge	'Okay, we set velocity on 9, ok, run [the model]'	22.86(11.49)

Table 2.

## Frequencies and examples of students' responses by level of epistemological understanding

Epistemological understanding	Examples	Frequency
1. Nature of Models		
Level 1	'A model is created by means of certain data'	6
Level 2	'A model is a simplified representation of reality'	17
Level 3	'A model predicts events that happen in reality, by using assumptions and calculations'	3
2. Purposes of Models		
Level 1	'With a model you do not have to measure everything and you can include everything in your model'	3
Level 2	'[A model is used] to obtain a clear overview of which variables are important'	12
Level 3	'[A model is used] to examine and discover relations and to make conclusions from the predictions made from a model'	11
3. Process of Modelling		
Level 1	'Modelling is to construct a model of something'	3
Level 2	'A model can be improved by adding new variables or relations'	21
Level 3	'By constructing simple models, you can use them for multiple purposes'	2
4. Evaluation of Models		
Level 1	'[Models are evaluated by] good looking at them and seeing that you did not left something out'	5
Level 2	[A model is correct] if all known factors have been included and when the model more or less corresponds with the empirical data'	16
Level 3	[A model is correct] if its output corresponds with the mean result of multiple (at least 200) measurements'	5
