ABSTRACT

This paper presents a comparative analysis of factors contributing to the innovation performance of manufacturing firms in Georgia (USA), Wales (UK), the West Midlands (UK), and Catalonia (Spain). Enabled by comparable survey data, multivariate probit models are developed to estimate how various types of firms' innovative activities are influenced by links to external knowledge sources, internal resources, absorptive capacity and public innovation support. Our results suggest the potential for mutual learning. For the European study regions there are insights about how universities in Georgia support innovation. For Georgia and Catalonia there are lessons from UK firms about better capturing potential complementarities between innovation activities. Additional implications for innovation measurement and knowledge base development are discussed.

actividades innovadoras de las empresas están influenciadas por los vínculos con fuentes externas de conocimiento, fuentes internas, capacidad absorbente y soporte público de innovación. Nuestros resultados indican que existe la posibilidad de un aprendizaje mutuo. Para las regiones europeas del estudio se puede aprender de qué modo las universidades en Georgia fomentan la innovación. Georgia y Cataluña podrían aprender de las empresas británicas a captar mejor las posibles complementariedades entre las actividades de innovación. Analizamos también las implicaciones adicionales para la medición de la innovación y el desarrollo de bases de conocimiento.

Knowledge, Capabilities and Manufacturing Innovation: A US-Europe Comparison

INTRODUCTION

Over recent years the internationalisation of product markets has contributed to intensified international competition, particularly from producers in low-cost countries. For firms in high labour-cost areas such as the US and Europe these pressures have reshaped firms' strategic options, de-emphasising cost-based competition and emphasising product design, performance and customer service (QUAH, 2001). Meeting the challenge of this increasing competition requires innovation in products, processes and the ways in which businesses organise and market their products. Moreover, recent work on innovation suggests that firms' ability to innovate depends not only on their own internal competencies but also on external knowledge sources and the quality of the innovation systems, networks and supply chains in which they are operating. In particular, the availability of external knowledge sources for innovation – such as universities, intermediate technology institutes, and standards setting bodies – have all been seen as significant enablers of innovation.¹

In this paper we focus on how firms in the US and Europe are able to innovate to meet the common challenges posed by intensified global competition. We explore firms' internal resources and capabilities, their absorptive capacity and the supportiveness of the innovation system within which they operate. More specifically, we compare the factors which contribute to the innovation performance of manufacturing firms in Georgia in the US South, the UK regions of Wales and the West Midlands, and the Spanish region of Catalonia. Each of these areas is broadly similar in terms of business R&D spending, and each is a region in which the

1
2 manufacturing sector, concentrated in traditional industries, is undergoing
3
4 considerable restructuring as a response to increasing international competition. In
5
6 Georgia, traditional sectors such as food processing, textiles, and pulp and paper
7
8 continue to dominate the manufacturing base combined with a high level of external
9
10 ownership (YOUTIE and SHAPIRA, 2007). In the UK West Midlands, a strong tradition
11
12 of metal-based industries, including the automotive sector, is giving way to a more
13
14 diverse, if smaller, manufacturing sector with limited new inward investment (LOVE
15
16 *et al.*, 2006). In Wales, inward investment has been more significant, attracted by an
17
18 intensive regional support regime, and has contributed to a shift in the industrial
19
20 sector from a traditional concentration in metals manufacturing and processing and
21
22 other heavy industries towards electronics and white goods production (COOKE *et al.*,
23
24 1995; COOKE, 2004; FULLER *et al.*, 2004). In Catalonia, the regional economy has
25
26 experienced profound change over the last two decades following Spain's entry to the
27
28 European Union (EU). The region's industrial structure is highly diversified and open.
29
30 Textiles, metalworking and food processing continue to be major employment
31
32 sources, but chemicals, transport equipment and machinery are also important in
33
34 terms of total industrial gross added value (BACARIA *et al.*, 2004).
35

36
37 For firms in these regions, facing intense international competition, broadly-
38
39 based innovation is necessary to upgrade product offerings and simultaneously
40
41 improve business efficiency and customer service (SHERGILL and NARGUNDKAR,
42
43 2005; BAKER and GILL, 2005). The research literature stresses the interdependence of
44
45 these different aspects of innovation, particularly those linked to human resource
46
47 management (HRM) and organisational innovation (DAWSON *et al.*, 2005), advanced
48
49 manufacturing techniques (AMT) and product innovation (MICHIE and SHEEHAN,
50
51 2003). Hence, in our empirical analysis we aim to capture the diversity of innovation
52
53
54
55
56
57
58
59
60

1
2 behaviours by considering product and process innovation alongside the adoption of
3 advanced manufacturing techniques, marketing approaches and organisational
4 structures. We model explicitly the potential complementarities between these
5 different types of innovation. ZENGER (2002), for example, suggests that we might
6 expect to see different patterns of complementarities between different types of
7 innovation leading to 'discrete organizational choices'. We also probe the role of
8 aspects of the innovation system external to the firm. Three empirical questions are
9 therefore addressed in the paper. First, what factors are shaping firms' innovation
10 activities in each study region? Second, what pattern of innovation complementarities
11 do we observe? And, third, how effectively are the relevant state and regional
12 innovation systems supporting firms' innovation activities?
13
14
15
16
17
18
19
20
21
22
23

24 Our empirical analysis is based on innovation survey data covering
25 manufacturing firms in each of the study regions - specifically, the Georgia
26 Manufacturing Survey, the UK Innovation Survey, and the Spanish Innovation
27 Survey. Much progress has been made in recent years in the design and conduct of
28 such innovation surveys, drawing on international standards established by the
29 Organisation for Economic Cooperation and Development and the EU Community
30 Innovation Survey. Nonetheless, some issues of international comparability inevitably
31 remain. This point should be kept mind in the interpretation of our results, particularly
32 where these depend on international comparisons.

2 data sources and empirical methodology. The final sections present our main
3
4 empirical results and conclusions.
5
6
7

8 9 **CONCEPTUAL APPROACH**

10 The starting point for our analysis is the now standard innovation production function
11 which reflects the process of *knowledge transformation*, in which knowledge sourced
12 by the enterprise is translated into innovation outputs of various types (GEROSKI,
13 1990; HARRIS and TRAINOR, 1995; LOVE and ROPER, 2001). The effectiveness of
14 firms' knowledge transformation activity is then influenced by the strength of the firm
15 and its ability to absorb external knowledge (LOVE and ROPER, 1999; ROPER et al.,
16 2006). In general terms, therefore, we can write the innovation production function for
17 an individual innovation output as:
18
19
20
21
22
23
24
25
26
27

$$28 \quad I_i = \phi_0'KS_{ki} + \phi_1RI_i + \phi_2ACAP_i + \phi_3GOVT_i + \varepsilon_i \quad (1)$$

29
30
31
32
33 Where I_i is an innovation output indicator, KS_{ki} are the sources of knowledge which
34 provide the basis for firms' innovation activity, RI_i is a set of indicators representing
35 the scale and scope of firms' internal resources, $ACAP_i$ is a set of indicators intended
36 to reflect firms' absorptive capacity – the ability to take in and apply new knowledge
37 (COHEN and LEVINTHAL, 1989, 1990; ZAHRA and GEORGE, 2002), $GOVT_i$ reflects
38 firms' access to public support for innovation and upgrading, and ε_i is the error term.
39 Sign expectations here are generally positive. In terms of the knowledge sources, for
40 example, we expect positive and significant signs where a knowledge source is an
41 important driver of firms' innovation activity. Similarly, where firms' internal
42 resources are strong, we would expect this to contribute positively to the efficiency
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2 with which firms are able to transform knowledge inputs into new innovations (LÖÖF
3 and HESHMATI, 2001, 2002). We also expect firms' innovation outputs to be positively
4 related to their absorptive capacity and the receipt of government support for
5 innovation or upgrading (see ROPER and HEWITT-DUNDAS, 2005).
6
7
8
9

10 A major limitation with the innovation production function in its standard
11 form is its focus on a single innovation output measure. Both empirical and
12 conceptual arguments suggest that this approach is limited and potentially misleading.
13 In empirical terms, for example, BROUWER and KLEINKNECHT (1996) demonstrate that
14 different innovation output measures may give a significantly different impression of
15 firms' relative 'innovativeness' and the determinants of innovation. They therefore
16 argue that in terms of empirical inference alone it is more appropriate to focus on a
17 'basket' of measures rather than a single innovation indicator (see also PITTAWAY et
18 al., 2004). However, this remains an unsettled issue. For example, FREEL (2005)
19 suggests that the determinants of product and process innovation are analogous, while
20 other recent research (FALK, 2006; SCHMIDT and RAMMER, 2006) finds similarities in
21 factors contributing to technological and organisational innovation. Nonetheless,
22 conceptual arguments for adopting a holistic multi-indicator approach to firms'
23 innovation activity remain persuasive, with a focus on the potential for tradeoffs
24 (HAYES et al., 1988) or complementarities between types of innovative activity
25 (MILGROM and ROBERTS, 1990, 1995).
26
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42

43 In terms of the innovation production function, this suggests the potential for
44 simultaneity between different forms of innovative activity, i.e. that *ceteris paribus* a
45 firm engaging in one type of innovative activity is either more, or less, likely to also
46 be engaging in other types of innovation. In behavioural terms, it is useful to envisage
47 firms' strategic decision to invest resources in each innovation activity as the outcome
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 of a comparison of the costs and anticipated benefits. LEVIEN and REISS (1984), for
4
5 example, derive first order conditions which relate the extent of firms' innovation
6
7 activity to anticipated price-cost margins. However, varied effects may result from the
8
9 mix of innovation activities adopted by firms. A tradeoffs perspective suggests the
10
11 pursuit of multiple innovation objectives at the same time risks mediocrity, and that
12
13 firms should therefore adapt more focussed priorities (HAYES et al., 1988). Similarly,
14
15 PORTER (1980) distinguishes competition based on cost versus differentiation,
16
17 advocating that companies either pursue one or the other competitive strategy (with
18
19 follow-on implications for innovation activity selection) in order to achieve a
20
21 leadership position.

22
23 A contrasting perspective emphasises complementarity, in other words, that
24
25 undertaking one form of innovation has either a positive effect on the anticipated
26
27 returns from another innovation activity, a negative effect on the costs of undertaking
28
29 that activity, or both (see SAMUELSON, 1974, on complementarity in economics). In
30
31 terms of anticipated returns, for example, the sales resulting from product innovation
32
33 may benefit positively from concurrent marketing innovation. ATHEY and
34
35 SCHMUTZLER (1995) examine the circumstances in which the implementation of
36
37 product innovation increases the likelihood that process and organizational innovation
38
39 will also be introduced. Their (theoretical) model suggests that flexibility in product
40
41 design and processes should, in most cases, result in subsequent innovations in
42
43 products and processes. Conversely, in terms of the costs of innovation, process
44
45 change might, for example, be more economically undertaken where it is
46
47 accompanied by either managerial or organisational changes. Based on a study of the
48
49 Spanish ceramic tile industry, MIRAVETE and PERMIAS (2004) develop a model to
50
51 discriminate between innovation complementarities and associations that stem from
52
53
54
55
56
57
58
59
60

unobserved factors. Their results suggest that product and process innovation are significantly complementary. For example, the single firing furnace (a technologically-oriented process innovation) gave rise to new product designs and organizational approaches to making these new products.

As the conceptual arguments are balanced, we regard the question of whether there are tradeoffs or complementary relationships between innovation activities as a matter for further empirical investigation. Our presumption, however, given the evidence of other studies is towards the likelihood of complementarities between types of innovative activity (e.g. FALK, 2006). In either case, modelling the possibility of trade-off/complementarity effects requires a generalisation of equation (1) to allow for simultaneity between innovation indicators

$$I_{ji} = \phi_{j0} KS_{ki} + \phi_{j1} RI_i + \phi_{j2} ACAP_i + \phi_{j3} GOVT_i + \phi_{j4} I_{ki} + \varepsilon_{ji} \quad (2)$$

Where j denotes a particular type of innovation activity and $j \neq k$. In equation (2), ϕ_{j4} will be positive for complementarities or negative for trade-off effects. Note also that we anticipate potential error covariance such that $E(\varepsilon_{ji}\varepsilon_{ki}) = \sigma_{jk}$. As our innovation output indicators are simple indicator variables suggesting whether firms are engaged in each particular type of innovation, the appropriate estimator is multivariate probit.

STUDY REGIONS

Our empirical study design examines our expectations and questions about firms' knowledge sourcing and innovation strategies in four regions: one in the US and three in Europe. This multi-regional approach allows us to probe relationships between internal knowledge and innovation strategies and external connectivity and, in

1
2 particular, to analyze the influence of differential regional support systems on
3
4 innovation strategies and outcomes. The choice of the US study region was shaped by
5
6 the availability of unique innovation survey data for Georgia manufacturing firms
7
8 (YOUTIE *et al.*, 2005). The European study regions were then chosen to reflect some
9
10 of the broad structural characteristics of Georgia's manufacturing sector. In the
11
12 selected European regions, as in Georgia, traditional industries are still important
13
14 despite recent restructuring, a significant number of externally-controlled (branch)
15
16 plants are present, there are numerous smaller industrial firms, and there are generally
17
18 low levels of R&D spending compared to other highly industrialized regions. Basic
19
20 structural statistics for each study region are presented in Table 1, which also provides
21
22 some indicators of the economic climate in the study regions at the time of the
23
24 comparison. For example, unemployment rates in the UK and US regions were
25
26 relatively similar, although there was more labour market inactivity in Catalonia. Per
27
28 capita incomes were also marginally higher in the US and UK West Midlands region
29
30 than in Catalonia and Wales. However, R&D intensity was quite similar across the
31
32 regions. An overview of each region follows.

33 34 35 36 **Georgia**

37
38 Georgia is the ninth largest US state and one of the fastest growing with a current
39
40 population of just over 9 million (Table 1). The development of the state has made it
41
42 emblematic of the American Sunbelt region's rapid expansion. However, much of the
43
44 recent growth has occurred in services, with continuing falls over the last few years in
45
46 overall manufacturing employment. In 2005, manufacturing accounted for around 13
47
48 per cent of Georgia's gross state product, a lower proportion than that in any of the
49
50 European study regions but comparable to the level for the US as a whole.
51
52
53
54
55
56
57
58
59
60

1
2
3 (Manufacturing value added comprised 12.1 percent of 2005 US gross domestic
4 product, see BUREAU OF ECONOMIC ANALYSIS, 2007.) In terms of the number of
5
6 establishments, Georgia's manufacturing sector is diverse. However, employment is
7
8 concentrated in the state's traditional resource-based sectors such as food processing,
9
10 textiles, and pulp and paper. These three industries accounted for 42 percent of
11
12 manufacturing jobs in the state in 2003 and more than half of rural Georgia's
13
14 industrial base. In addition, the US South is known as a region of branch plants and in
15
16 Georgia more than 40 percent of manufacturing units are branch plants.
17

18
19 Private sector research and development (R&D) is lower in Georgia than in
20
21 much of the US, although levels of university R&D are closer to the US average
22
23 (Table 1). Although Georgia ranked ninth in population in 2003, it ranked 22nd in the
24
25 level of industrial R&D (NATIONAL SCIENCE FOUNDATION, 2006) The industrial
26
27 make-up of Georgia's industry contributes to the state's relatively low ranking in
28
29 terms of private R&D. Nationally, company expenditures for R&D as a percentage of
30
31 net sales were 0.47, 0.82, and 1.06 respectively for Georgia's three traditional
32
33 industries of food processing, textiles and wood products, compared with 3.63 for all
34
35 US industries (NATIONAL SCIENCE FOUNDATION, 2005, Table A-2). Over the last two
36
37 decades, Georgia has developed a series of policies, programs and public-private
38
39 partnerships to expand research-based high technology industries in the state, with
40
41 some success in recent years in increasing high tech start-ups particularly in Atlanta,
42
43 the state's largest metropolitan region. Georgia has also developed (with federal and
44
45 state funds) an extensive manufacturing extension system, organized by the state's
46
47 leading technological university (Georgia Institute of Technology), to provide
48
49 industrial support and knowledge transfer services to existing manufacturing
50
51 establishments (SHAPIRA, 2005).

60

Wales

Wales is the smallest of the four study regions in terms of population (2.95m), has the lowest workforce employment rate, and a relatively low per capita income (Table 1).

It is one of the 'devolved' territories of the UK with considerable discretion over most aspects of social and economic policy (although see MORGAN, 2002). This has led to regional policies focussed on promoting inward investment in high-tech sectors, strengthening the skills base and encouraging innovation and enterprise (COOKE *et al.*, 1995; COOKE, 2004). The effectiveness of this policy strategy has been questioned (see, for example, FULLER and PHELPS, 2004) but it is clear that inward investment has been a major factor in reshaping the Welsh manufacturing sector over recent years. BRAND *et al.* (2000), for example, suggest that in 1995, 39 per cent of the output of manufacturing industry in the sectors they considered was generated by externally-owned firms which accounted for 29 per cent of total employment. Manufacturing inward investment to the region has been concentrated in two main sectors (electronic and electrical engineering and automotive components) although there have also been large-scale investments in other transport sectors (e.g. aeronautical engineering).

In 2003, manufacturing accounted for more than 18 per cent of GDP in Wales, considerably more than that in Georgia but around the same level as the West Midlands (Table 1). Levels of R&D spending in Wales are similar to those in Georgia and Catalonia but generally lower than the UK average both in terms of business and higher education R&D spending.

The West Midlands

1
2 Often described as the manufacturing heartland of the UK, the West Midlands has a
3
4 population of just over five million, larger than that of Wales but smaller than Georgia
5
6 and Catalonia (Table 1). Levels of economic activity in the region are high, as
7
8 measured by the workforce employment rate, and this contributes to an average per
9
10 capita income that is greater than for Wales. Traditionally, the West Midlands
11
12 manufacturing sector had a strong focus on metal-based industries, with a significant
13
14 automotive sector. Recent high profile plant closures (including the 2005 collapse of
15
16 the MG-Rover Group) have reduced this emphasis somewhat but manufacturing
17
18 remains concentrated in traditional medium-tech, engineering sectors. Manufacturing
19
20 inward investment to the region has been less important than in Wales and strongly
21
22 concentrated in the automotive sector and related industries (BRAND *et al.*, 2000).
23

24
25 Reflecting the composition of industry in the West Midlands, levels of R&D
26
27 spending in the region are similar to those in Wales, Catalonia and Georgia, and
28
29 below the UK average (Table 1). Recent commentaries on this have tended to
30
31 emphasise the difficulty this suggests for firms' absorptive capacity – a factor which,
32
33 in the West Midlands, is exacerbated by relatively low workforce skill levels (LOVE *et*
34
35 *al.*, 2006).
36
37

38 ***Catalonia***

39
40 Catalonia remains the most industrialized among the study regions (Table 1), despite
41
42 as in the other regions, the relative importance of manufacturing has fallen in recent
43
44 years as services have grown. Catalonia's manufacturing base is still significant in
45
46 regional and national contexts. In 2003, manufacturing industries employed 23.2
47
48 percent of total regional employment and accounted for 23.4 percent of regional gross
49
50 value added, representing more than 25 per cent of Spain's industrial gross value

added. Many types of manufacturers operate in Catalonia, although the region is most specialized in medium-high and medium-low-technology industries.

Catalonia is known for its strong entrepreneurial tradition and the importance of small and medium enterprises, often family owned. Of the region's industrial firms, more than half of employ fewer than five workers and just less than one per cent employ more than 200 workers. Numerous types of industrial networks of collaborating firms have been identified in the region, including public, private and semi-public organizations (BACARIA, *et al.*, 2004). Firms' high level of industrial association, and the diverse nature of networking organisations, seem to be signalling the existence of high levels of social capital in the region. The systemic nature of industrial relations has been studied under the " regional innovation systems" framework, leading to the conclusion that this concept is applicable for Catalonia (BACARIA, *et al.*, 2004).

The openness of the system has been increasing since Spain's 1986 accession to the European Union and the creation of the European Single Market in 1993. Since then Catalan firms have become more internationalised, currently, exporting more to the European markets than to the national market. Foreign direct investment into the region is also significant, and now plays an important part in the technology acquisition model. However, when knowledge indicators are considered, the picture is quite different. In a recent study FERNANDEZ-RIBAS AND SHAPIRA (2007) find that Catalan firms rarely cooperate with foreign partners as part of their innovation activity. Catalan firms seem to be facing considerable challenges to access European competitive public R&D funding and to set up partnerships with foreign partners.

While Catalonia remains a major manufacturing region, like the other three study regions it has pursued a medium-level technological path. At 1.2% of gross

1 regional product, the overall level of R&D expenditure in the region is lower than the
2 European average, but similar to Georgia, Wales and West Midlands (Table 1).
3
4
5
6 Traditionally, the region's exporting capacity has been based on competing through
7
8 low labour costs and prices coupled with high productivity in mature industrial sectors
9
10 such as chemicals and transport equipment (FERNANDEZ-RIBAS, 2003). However, this
11
12 model is under increasing competitive pressure from new EU members and other non-
13
14 EU countries that have cheap yet skilled human capital. Catalan's current human
15
16 capital level does not seem sufficient to facilitate the transition to new innovation
17
18 models based on competition via high-value added products. In fact, the region has a
19
20 growing relative disadvantage in specialized human capital and scientific personnel.
21
22 However, it is also worth noting that the informal nature of innovation and R&D in
23
24 Catalan SMEs is not well captured by official R&D statistics. In this regard, the
25
26 broader measures of knowledge sourcing and innovation analyzed in our study should
27
28 give a fuller picture of the strategies of regional manufacturers, as the following
29
30 section discusses.
31
32
33

34 **DATA AND METHODS**

35
36 The common element in the multi-regional data used in our study is that all our
37
38 sources are based on innovation surveys. In contrast to conventional indicators of
39
40 R&D spending or patenting, innovation surveys seek to track a broader range of
41
42 innovation capabilities and performance including the development and application of
43
44 new product, process, organizational, and marketing innovations at the enterprise
45
46 level. A primary reference point for innovation surveys is the 'Oslo Manual' – a set of
47
48 guidelines established by the Organization for Economic Cooperation and
49
50 Development (OECD) for collecting data on technological innovation (see OECD,
51

2005). More than 50 countries have undertaken innovation surveys (MOHAPATRA *et al.* 2006) using these guidelines, including member states of the European Union through the Community Innovation Survey (CIS). The CIS has a two-fold purpose: (1) to monitor the level of innovation within private sector firms and (2) to provide a statistical basis for innovation policy. The first CIS was conducted in Europe in the 1992-93 timeframe; this survey is currently in its fourth iteration and the fifth CIS is planned for 2008 (see, for example, EUROPEAN COMMUNITIES, 2004)

For the US, there is no equivalent to the European CIS. National surveys conducted by the Census Bureau or the National Science Foundation incorporate elements related to innovation (such as R&D expenditures), but they do not as yet seek to measure the full range of innovation-related activities. To the best of our knowledge, the only innovation survey that has been conducted with consistency in the US – and which uses questions comparable to those of the CIS – is the Georgia Manufacturing Survey. This has been conducted in Georgia in 1994, 1996, 1999, 2002 and 2005 (with a 2008 round planned). For our study, data is taken from the 2005 Georgia Manufacturing Survey. This is a postal survey of manufacturing establishments in the state with 10 or more employees, with responses being weighted to reflect the industry-employment size distribution of firms as reported in the Georgia Department of Labour’s ES202 database (which is collected under a federal-state programme and comprehensively covers all employers hiring workers subject to state unemployment insurance provisions). The Georgia Manufacturing Survey is addressed either to a senior manager by name or to the title “general manager,” with survey responses completed by the CEO, managing director, general manager, plant manager or other senior manager of the facility. Data presented in this paper is based

1
2 on an analysis of 653 manufacturing establishments whose management responded to
3
4 the 2005 Georgia Manufacturing Survey (see also YOUTIE, *et al.*, 2005).

5
6 Our study data for Wales and the West Midlands is drawn from the 2005 UK
7
8 Innovation Survey, the latter being part of the fourth CIS wave. The 2005 UK
9
10 Innovation Survey covers the majority of sectors of the UK economy, targeting the
11
12 senior managers of enterprises with more than 10 employees (ROBSON and ORTMANS,
13
14 2006). The sampling frame for the survey was developed from the official
15
16 interdepartmental business register, with the survey being conducted by post. The
17
18 overall response rate was 58 per cent (16,446 responses) although no sectoral
19
20 breakdown of this is available. Weights were developed to give regionally
21
22 representative results. The analysis reported here is based on the 413 responses by
23
24 Welsh manufacturing firms, and the 559 responses by West Midlands manufacturers.
25

26
27 Data for Catalan firms comes from the third wave of the Spanish Innovation
28
29 Survey. The Spanish Innovation Survey covers manufacturing and service firms with
30
31 more than 10 employees for the period 1998-2000. Firms that do not report new or
32
33 significantly improved innovation products or processes do not have to answer the
34
35 whole questionnaire, including questions about innovation expenditures, R&D, effects
36
37 of innovation, public support to R&D, R&D cooperation, and sources of information
38
39 for innovation. Our analysis for Catalan firms is therefore restricted to those that
40
41 reported product or process innovation, a group of 930 manufacturing firms in all.
42
43 The more specific nature of the Catalan data somewhat limits the direct compatibility
44
45 with the US and UK study regions, essentially narrowing the range of indicator
46
47 strategies encompassed by the analysis. For example, Catalonian firms engaging
48
49 solely in organisational innovation without either product or process change are
50
51 excluded from the analysis. This limitation to the Catalan data is likely to affect the

assessment of complementarities since the range of innovation strategies included in
the Catalan data is somewhat reduced. Nonetheless, the Catalan case serves to
illustrate how the value chain model behaves for a sub-sample of product and process
innovators.

34
In all comparative survey-based studies, such as that reported here, data
comparability is a major issue. Previous work has used matched data across multiple
CIS and other innovation surveys (ROPER and HEWITT-DUNDAS, 2006). The three
surveys used in our analysis are consistent with OECD and CIS guidelines which
provide a common set of definitions of product and process innovation.² Recent
additions have seen the incorporation of organizational innovations – including
strategy, management, structures and marketing – to the standard definition of
innovation.³ Descriptive data for innovation activities and a range of explanatory
factors for these firms is presented in Table 2. For each region, we model firms'
participation in five different types of innovation activity representing the adoption of
AMT, organisational innovation, marketing innovation, product innovation and
process innovation using simple binary dummies.

Overall proportions of firms undertaking each type of innovation are very
similar in the two UK study regions with product and process change the most
common and AMT adoption least common. Percentages are higher for the Catalan
region as they refer to product and process innovators. For Georgia, the proportions of
innovating firms are notably higher for each type of innovation. This is consistent
with other US-UK comparisons which have suggested that US firms are in general
marginally more innovation-active than UK firms (e.g. CAMBRIDGE-MIT, 2006).
Reassuringly, however, despite these levels differences, the ordering of innovation
types among manufacturing firms in Georgia is identical to that in the UK study

1
2 regions and broadly similar to that in Catalonia (Table 2). Note also the generally
3 strong and positive correlation coefficients between our different innovation
4 indicators suggesting complementarities between the different innovation activities
5 (Table 3). Notably the one exception to this general pattern is the negative correlation
6 between product and process innovation in Catalonia.
7
8
9
10
11

12 A key driver of innovation is knowledge sourced outside the firm, and here we
13 distinguish between six routes through which firms are able to source the knowledge
14 needed for innovation (ROPER, *et al.*, 2006). First, in-house *research and*
15 *development (R&D)* may create new knowledge but may also help to increase firms'
16 absorptive capacity. R&D is defined as "creative work undertaken within the
17 enterprise to increase the stock of knowledge and its use to devise new and improved
18 goods, services and processes."⁴ Second, knowledge transfer from *other group*
19 *members* – from other companies or units within the firm's enterprise group – may
20 enable a firm to benefit from R&D undertaken elsewhere in a multi-plant or multi-
21 national company. Third, *forwards links*, defined as knowledge sourced from
22 customers or clients, may assist firms in innovation through a better appreciation of
23 customer requirements or market trends. Fourth, *backwards links*, defined as
24 knowledge sourced from suppliers of equipment, materials, services, or software, may
25 enable firms to identify new technologies or potential process changes. Fifth,
26 *horizontal links*, defined as knowledge sourced from competitors or joint ventures,
27 may suggest new market opportunities. Finally, firms' links to *public knowledge*
28 *sources*, such as universities, public sector laboratories, or technology programmes, as
29 part of their innovation activities may provide access to leading edge technologies or
30 technical assistance.

Profiles of knowledge sourcing in Wales and the West Midlands are, like those for innovation, relatively similar with West Midlands firms less likely to engage in R&D but more likely to engage in external knowledge sourcing than those in Wales (Table 2). Firms in Georgia exhibit a more extreme pattern with R&D less common than in either of the two UK study regions but stronger patterns of connectivity to other firms. Catalonia shows yet another pattern of results in terms of knowledge sharing. Backward, forward and horizontal linkages are uniformly less common than in the UK regions and Georgia. Interestingly, the percentage of firms with cooperative agreements with public knowledge sources is higher in Catalonia than in the UK regions, in part due to the growing tendency to subcontract basic and applied research to universities and also the regional government's promotion of an R&D subcontracting market (FERNANDEZ-RIBAS, 2003). However, significant effects from such agreements are, as yet, not picked up in the innovation survey data.

These results seem to suggest that Catalonia is not as advanced in terms of connections for innovation, despite being a region with abundant industry networks for purposes of procurement and supply. Our statistical analysis finds that Catalan firms do not seem to take full advantage of the innovation potential of business inter-relationships. Rather they show a traditional cooperation pattern limited to information sharing and low value added activities. *A priori*, we would expect the higher level of connectivity among firms in Georgia to be contributing positively to higher innovation rates. In terms of firms' resources it is clear that firms in Georgia are on average smaller (in 2002 at the start of the period) and older than those in the two UK study regions (Table 2). On the basis of previous studies, we would expect both factors to be reducing levels of innovation in Georgia relative to the UK. Other resource and absorptive capacity indicators are broadly similar for firms in Georgia

and the UK regions and Catalonia. Overall, therefore, our descriptive analysis suggests that higher levels of innovation among firms in Georgia may be linked to higher levels of connectivity and knowledge sharing.

In addition to the direct drivers of innovation we are also interested in potential complementarities between types of innovation activity, in other words the significance of ϕ_{j4} in equation 2. In practice, however, we experienced substantial difficulty in obtaining convergence with the full degree of simultaneity implied by equation 2 in a multivariate probit. Instead, therefore we develop a more general indication of complementarities based on a series of alternative variables $C_{ki}, k=1,5$ where $C_{ki} = 1$ if $I_{ji}=1$ for any $j \neq k$, and 0 otherwise. In other words, C_{ki} takes value 1 where a firm is engaged in any of the other forms of innovation, and 0 if the firm is not engaging in any of the other forms of innovation. (See Table 2 for descriptives.) Coefficients on C_{ki} therefore provide a more generalised view of complementarities or trade-offs between different types of innovation than the ϕ_{j4} of equation 2. Our final estimating equation is therefore the five-equation multivariate probit model ($j=1,5$):

$$I_{ji} = \phi_{j0} KS_{ki} + \phi_{j1} RI_i + \phi_{j2} ACAP_i + \phi_{j3} GOVT_i + \phi_{j5} C_{ki} + \varepsilon_{ji} \quad (3)$$

Where, as before, we anticipate potential error covariance such that $E(\varepsilon_{ji}\varepsilon_{ki}) = \sigma_{jk}$.

EMPIRICAL RESULTS

Tables 4, 5 6 and 7 give multivariate probit estimates for Georgia, Wales, the West Midlands, and Catalonia respectively, and Table 8 summarises the results symbolically. In general terms the multivariate probit models perform relatively well, significantly outperforming random assignment and identifying a range of significant

1
2 factors. Significant error covariances also suggests the value of the simultaneous
3
4 estimation approach rather than single equation probit models.⁵
5
6
7

8
9 The first aspect of interest in the models is the potential complementarity between
10 types of innovation, and it is here that we see the strongest contrasts between the four
11 regions. In the UK regions of Wales and the West Midlands, reflecting the pattern of
12 previous European studies (FALK, 2006; SCHMIDT and RAMMER, 2006) we find
13
14 positive and significant complementarities between all five types of innovation
15
16 suggesting perhaps economies of scope in the management of innovation or more
17
18 functional or operational complementarity. In Georgia, we find a more neutral pattern
19
20 with no evidence of such complementarities. Several explanations are possible. For
21
22 firms in Georgia, it may be that functional separation in management is more strongly
23
24 maintained than for the UK firms in the study. In this case, where managers focus
25
26 solely on their own functional area with little input into other areas, this might reduce
27
28 the potential for cross-functional learning by management from innovation in other
29
30 aspects of firms' activities. Alternatively, it could be that the strategic intent
31
32 underlying innovation in firms in Georgia is more focussed than that in the UK. For
33
34 example, if innovation in firms in Georgia was more focussed on process
35
36 development than in the UK study regions (Table 2) this might have less synergy with
37
38 other forms of innovation than product change which seems predominant in the UK.
39
40 Catalan firms also demonstrate few innovation complementarities, but the strength of
41
42 this result should be put in the context of product and process innovators.⁶ The
43
44 Catalan case adds a new layer to our model in that it seems to be indicating that for a
45
46 near-to-market innovation model the private value of complementarities is more
47
48 limited. Positive externalities between product and process innovation do not emerge,
49
50
51
52
53
54
55
56
57
58
59
60

1
2 suggesting that product and process innovation are reaching different types of firms
3 and different types of innovation projects. Estimation results indeed suggest that
4 product innovation and process innovation are largely driven by different factors.
5
6 Product innovation is more likely among firms that do research activities and firms
7 that invest capital on innovation. Process innovation is more likely among non-R&D
8 performers and firms from low-tech sectors. Firms that have some kind of knowledge
9 absorptive capacity and train their employees also have significantly more chances to
10 do process innovation. Asymmetries between both types of innovation are also
11 manifested in the negative and highly significant correlation coefficients (Table 2).⁷
12
13 One possible interpretation of these points is that innovating firms in Catalonia do not
14 appear to be managing highly technologically-complex projects that require complex
15 organizational structures; rather they seem to have a traditional innovation strategy
16 focused on technology adaptation and development of incremental technological
17 innovations that are highly applied and near-to-market.
18
19
20
21
22
23
24
25
26
27
28
29

30
31 Other determinants of innovation suggest a more uniform picture across the
32 four study regions. In terms of knowledge sourcing, for example, in-house R&D is
33 consistently important, although its effects are notably stronger in Georgia than in
34 either of the European study regions. This is consistent with other studies of the
35 determinants of firms' innovation activities, which consistently envisage R&D as a
36 key direct driver of innovation (LÖÖF and HESHMATI, 2001, 2002) and as an important
37 determinant of absorptive capacity (CASSIMAN and VEUGELERS, 2002). As noted
38 earlier, this latter point may be particularly significant in Georgia, where links
39 between firms, and between firms and elements of the public knowledge base, seem
40 better developed than those in the European study regions (Table 2).

In terms of firms' external links, and their impact on innovation we also find some similarities between the four study regions. Backwards linkages – to suppliers – for example, have positive and significant benefits for product change in each of the study regions, (except for the Catalan region) but are less strongly linked to organisational and market innovation or the adoption of AMTs. Forward linkages to clients or customers have less consistent benefits across the study regions but have positive impacts on product change (West Midlands and Georgia), AMT (Catalonia), organisational structure (West Midlands, Catalonia and Georgia) and marketing (Georgia). Interestingly, forward linkages do not appear so important for Welsh firms, although horizontal links appear most important for firms in Wales. This is of particular interest given the strength of policy initiatives in Wales to try and develop innovation networks and support collaborative working between firms (MORGAN *et al.*, 2000). Equally important, however, is the general weakness of the contribution to innovation of firms' links to public knowledge sources, most notably the universities. In both the UK study regions these links are consistently insignificant, with the only significant, and positive, effect being on process innovation in Georgia. This result is consistent with the profile of support offered by the university-sponsored industrial services to firms in Georgia, which tend to focus on process change and optimisation (for instance, by promoting lean manufacturing). However, it is disappointing given the policy emphasis on developing more advanced university-company knowledge transfer activities in recent years on both sides of the Atlantic (LAMBERT, 2003; O'SHEA *et al.*, 2005).

For firms' resource base, we find evidence that scale factors – related here to firm size at the start of the period – are most significant in terms of process innovation and innovation in organisational structures (Table 8). More generally, we find the

standard inverted ‘U’ shape relationship between the probability of innovating and firm size noted elsewhere in the innovation literature (see KIM *et al.*, 2004). Plant vintage is generally unimportant, but perhaps more interesting is the lack of very positive evidence of any consistent benefit to innovation from either group membership (or intra-group knowledge transfers). This is important given an argument in the academic literature on multi-national enterprises which suggests that intra-firm knowledge transfers are by-and-large effective and that, as a result, plants within multi-national groups tend to be more innovative and productive than similar independent operations (HEWITT-DUNDAS *et al.*, 2005).

Absorptive capacity effects prove more consistently important particularly related to firms’ investments in innovation related training and capital (Table 8). This serves to emphasise the importance of high quality human capital for innovation (see also FREEL, 2005) and the importance of related capital investments particularly as part of process change. What is less clear from our econometric evidence is the mechanism by which these effects are operating, in other words whether they represent an absorptive capacity effect, or whether they are activities directly correlated – or part of – particular innovation projects⁸. For example, it may be that undertaking training for innovation and capital investment enable, or make it easier, for firms to evaluate and implement innovation ideas gleaned from other firms or other external knowledge sources. In this situation, training and investment are enhancing firms’ general absorptive capacity but may have no direct role in terms of specific innovation projects. In fact, our econometric evidence suggests that both effects may be operating, i.e. that project specific investments in training and capital equipment may also be having wider absorptive capacity effects. In particular, we see positive and significant training and investment effects in projects relating to process

innovation, but weaker – perhaps absorptive capacity effects – on other forms of innovation activity.

Finally, our evidence on public support for innovation (including through grants, loans, loan guarantees and subsidies) is limited to the European study regions. In general terms, this public support for innovation has a positive effect, increasing the probability that firms will engage in each type of innovation.⁹ Perhaps the most interesting aspect of our results, however, is the apparent weakness of local or regional support measures for innovation, and the greater significance of national and supranational (European) support measures for innovation. The implication is that locally-oriented or organised measures – presumably focussed on either stimulating local innovation or connectivity – are actually less effective at stimulating innovation than measures designed to promote broader national (for example, the UK's Collaborative Research and Development programme) or international collaboration for innovation (for instance, through various initiatives of the European Union's Framework programmes). A potential explanation is that at a regional level it may be difficult to find appropriate – or high quality – partners for innovation, although these may be available nationally or internationally. This is consistent with the arguments made in COE and BLUNDELL (2003), which while recognising the importance of proximity to innovation also argue that trans-national innovation linkages can play an important role in knowledge creation (see also OINAS, 1999). In the context of Wales and the West Midlands, the empirical results of OERLEMANS et al (2003), are also relevant here. Based on Dutch data they suggest that localised innovation linkages are more important where innovation is highly complex. As indicated earlier, however, both the West Midlands Wales and Catalonia are generally low R&D intensity regions with a concentration of manufacturing activity in medium-to-low R&D-intensity

1
2 industry. In this context, the results of OERLEMANS et al. (2003) suggest that local
3
4 innovation networks might be less important than in regions with a stronger
5
6 concentration of R&D-intensive manufacturing.
7
8
9

10 **CONCLUSIONS**

11
12 In this paper we have addressed three main empirical questions, the first of which
13
14 related to the dynamics and determinants of innovation in manufacturing firms in
15
16 Georgia, Wales, the West Midlands and Catalonia. The second question probed the
17
18 potential complementarities between different types of innovation. The third question
19
20 examined the effectiveness of broader innovation systems in supporting
21
22 manufacturing innovation in each of the study regions. In each case the reliability of
23
24 our results depends on the international comparability of the innovation survey data
25
26 we use for our analysis and we would stress the exploratory nature of our analysis.
27
28 Each of the three surveys we use is, however, based on a standard set of definitions of
29
30 innovation derived from OECD and EU guidelines and have identical target
31
32 populations. Nonetheless, some caution is still relevant in interpreting the results due
33
34 to potential differences in the way firms in each country respond to such surveys and
35
36 differences in firms' operating environments.
37
38

39 In the analysis of our first question, overall, we find that Georgian firms have
40
41 a slightly higher probability of undertaking innovation than their UK counterparts in
42
43 terms of product, process, marketing, business organisation and the adoption of
44
45 AMTs. Interestingly, however, the relative proportions of firms undertaking each type
46
47 of innovation in the US and UK study regions are very similar. Results for the Catalan
48
49 region complement these findings for a sample of product and process innovators. Our
50
51 innovation production functions suggest two main factors which seem to be
52
53
54
55
56
57
58
59
60

1
2 contributing to these higher levels of innovation in US firms. First, in the models we
3 see significant and positive effects from firms' knowledge sourcing activities (Table
4 7), with the descriptive analysis suggesting that US firms have a generally higher
5 level of external connectivity than that in UK and Catalan firms (Table 2). One
6 possibility therefore is that the higher degree of 'association' (COOKE and MORGAN,
7 1999) between firms in Georgia may be contributing to higher levels of innovative
8 activity in the region. Second, in Georgia we also see the only significant positive
9 contribution from public knowledge sources to innovation (Tables 4 and 7) and this
10 again is likely to be contributing to higher innovation propensity in the US, at least in
11 terms of process change. Other factors, such as firms in-house R&D and training and
12 investment as part of firms' innovation activities prove important in each of the four
13 study regions (Table 8). In evaluating these results it is important to acknowledge the
14 context for our US- European comparison, i.e. the comparison is between regions in
15 which manufacturing industry is restructuring and retains a strong presence in more
16 traditional sectors. Earlier caveats regarding the international comparability of
17 innovation survey data are also relevant here.

The second question focussed on potential complementarities between different types of innovation. Our prior was based on the likelihood of managerial learning to generate economies of scope between different forms of innovation activity, or the potential for functional synergy between different innovation activities. In our empirical results, we see markedly different patterns between the study regions: in both UK study regions we observe strong positive complementarities between different types of innovation activity; in Georgia we see no evidence of any such complementarities (Table 8). Potential explanations relate either to stronger functional separation in management in US firms – and therefore a failure to capture or transfer

1
2 knowledge from one aspect of innovation to another – or to a more focussed approach
3
4 to innovation in US firms than that adopted in the UK. In either case, our evidence
5
6 suggests that US firms may not be taking full advantage of potential synergies
7
8 between their innovation activities, something which is being achieved by firms in
9
10 Wales and the West Midlands. A closer look at the sub-sample of product and process
11
12 innovators gives an additional twist to our findings. Results for Catalan innovator
13
14 firms indicate that complementarities between product and process may not be fully
15
16 exploited when firms pursue very applied innovation strategies. Again, however, we
17
18 would stress the exploratory nature of these observations.
19

20
21 Our results do allow us to depict the study regions in terms of their profiles of
22
23 internal innovation synergies and external connectivity (Figure 1). None of our study
24
25 regions score ‘high’ on each dimension, the type of position suggested for leading
26
27 high technology regions by the open innovation model (CHESBOROUGH, 2003).
28
29 Rather, our regions assume other positions on this matrix of possibilities. The UK
30
31 regions of Wales and the West Midlands exhibit high internal innovation synergies
32
33 with low external connectivity. Diagonally opposite is Georgia, with low internal
34
35 innovation synergies and high external connectivity. On these measures, Catalonia
36
37 trails the study group, with low performance in both external connectivity and, as far
38
39 as we can assess it given the nature of the Catalonian sample, low internal innovation
40
41 synergy. Another way of interpreting these results is in terms of the notion of the
42
43 innovation funnel which illustrates the process by which an initial set of ideas are
44
45 evaluated, tested and finally result in innovation (HAYES *et al.*, 1988). The shape of
46
47 the innovation development funnel can then be used to provide an indication of the
48
49 breadth of the set of initial ideas being considered by a firm and the degree of attrition
50
51 during the innovation process. In Georgia, the suggestion of greater connectivity
52
53
54
55
56
57
58
59
60

1
2 among firms suggests a broader set of knowledge inputs to the innovation process
3
4 than in the UK study regions, however, the more focussed approach to innovation
5
6 being adopted in Georgia also suggests greater attrition or the elimination of
7
8 innovation ideas. In the UK study regions, the lower level of connectivity suggests a
9
10 narrower range of initial knowledge inputs to the innovation process; while the less
11
12 focussed approach to firms' final innovation outputs suggests less attrition, or a
13
14 development funnel which narrows more slowly. Catalonia is yet another case.
15
16 Neither the use of external knowledge sources nor the level of synergies across
17
18 innovative activities appears to be high. The lower external connectivity, as seen in
19
20 the UK regions, is not *per se* inhibitory in further development of complementarities,
21
22 but in this case it seems to be connected.
23

24
25 These differences in innovation behavior between US and European firms,
26
27 however tentative, are worthy of some further comment. Why is, for example, that
28
29 firms with, presumably, similar profit maximizing objectives adopt such contrasting
30
31 innovation strategies? At least two explanations are plausible. First, there may be
32
33 differentiated access to technical and market information between US and European
34
35 firms. These informational asymmetries may be leading to the development of
36
37 different innovation strategies. Second, and to the point of this study, it may be that
38
39 there are important national and regional innovation system differences which are
40
41 impacting on the innovation practices of firms, the way they access knowledge, and
42
43 the relevance of local institutions such as universities. The contrasts in innovation
44
45 behavior observed here also raise a further question: Is it better for firms to adopt a
46
47 focused innovation strategy or one which is more broadly-based? For example, it
48
49 might be argued that a more focused innovation strategy might allow a firm to move
50
51 an innovation more quickly and flexibly into a market, such as in the case of new
52
53
54
55
56
57
58
59
60

1
2 product introduction. This might be particularly true for small and medium-sized
3
4 firms where limited absorptive capacity might make project-based, rather than
5
6 portfolio-based, innovation a more realistic possibility. On the other hand, a more
7
8 broadly-based innovation strategy might have better long-term payoffs, allowing
9
10 firms to benefit from translating learning from one type of innovation to another.
11
12 More importantly this approach suggests that there is a broader strategy that impacts
13
14 firm decisions and innovation choices. Innovations may be better planned and
15
16 executed under a holistic approach that takes into account not just product
17
18 development (for example) but also how this product will affect processes,
19
20 organizational structures, and marketing. This added level of integration may justify
21
22 the effectiveness of the holistic strategy in the long-term.
23

24
25 Our third empirical question related to the effectiveness of the relevant state
26
27 and regional innovation systems in supporting manufacturing innovation in each of
28
29 the study regions. Two observations are relevant here. First, it has been argued that a
30
31 key element of such local or regional innovation systems is the degree of association
32
33 or linkage between firms, and our innovation production function estimates support
34
35 this view emphasising the importance of external connectivity for innovation (Table
36
37 8). Of our four study regions, however, we see from the descriptive analysis the
38
39 strongest external connectivity among firms in Georgia (Table 2), suggestive of a
40
41 greater degree of knowledge sharing or diffusion among US firms than that evident in
42
43 the UK and Spain. This inter-firm connectivity clearly matters for innovation given
44
45 the positive and significant coefficients on the forwards, backwards and horizontal
46
47 knowledge sharing terms in the probit models. Second, in terms of the contribution of
48
49 public knowledge sources including universities to regional innovation we see
50
51 stronger effects in Georgia than in either of the two UK study regions or Catalonia,
52
53

although, as noted, earlier this effect is specific to process change. Our interpretation is that the greater degree of association between firms and the more positive contribution from public knowledge sources to innovation suggests a more supportive innovation milieu in Georgia than in the other study regions. Again, however, it is important to take into account the fact that each of the study regions is a restructuring region with relatively low levels of high-tech manufacturing activity and R&D spending.

More generally, our results suggest something of a contrast. Firms in Georgia seem from our results to benefit from a more supportive external environment for innovation than firms in Wales and the West Midlands characterised by more knowledge sharing but do not exploit to the full potential complementarities between their innovation activities. For the European study regions there are therefore potential lessons here in terms of the way in which the universities in Georgia – and potentially other public knowledge providers – are supporting innovation in manufacturing firms. It may also be useful to explore further the reasons for the differential levels of connectivity between US, Spanish and UK firms. For firms in Georgia and Catalonia the potential lessons are more strategic or organisational. Why is it that UK firms are able to capture complementarities between their innovation activities which are not being captured by firms in Georgia and in Catalonia? Answering this latter question is likely to require more detailed and comparative case-study evidence than that currently available and it may also be useful to broaden the range of regions covered in future analysis to examine the generality of the patterns identified here to other UK and European regions. It is also important to acknowledge that the comparison conducted here is essentially cross-sectional, and will inevitably reflect economic conditions at the time the surveys were undertaken. It would therefore be useful to re-

1
2 consider the results obtained here in a more longitudinal context. This would help to
3 confirm causality between the variables considered here and also better account for
4 the impact of economic context and market change on outcomes.
5
6
7

8
9 Finally, our results also raise an important measurement issue for
10 consideration at national policy levels. Innovation has traditionally been represented,
11 particularly in the US, by indicators such as patents, venture capital, and R&D. Based
12 on measures such as these, which tend to have an exclusively technological
13 orientation, the US as a whole emerges as a global leader, giving rise to concerns
14 about an innovation between the US and Europe (MERIT, 2006). On such metrics,
15 leading US technological regions (such as California's Silicon Valley or
16 Massachusetts' Route 128) do well, while other US regions such as Georgia display
17 middling or weak performance. Yet this study has shown that, using a broader array
18 of metrics, innovation does take place within Georgia manufacturers in important
19 areas such as knowledge sourcing that are not picked up by conventional high
20 technology innovation indicators. Moreover, there is something distinctive about the
21 regional system within which Georgia firms operate relative to similar firms in the
22 West Midlands and Wales with respect to the complementarities between innovation
23 types. This level of information is obtained through the benchmarking of items in
24 innovation surveys, particularly the analysis of a variety of innovation activity and
25 knowledge linkage measures. Innovation surveys have attracted increased interest in
26 the US recently, as debate has grown about improving and broadening measures of
27 science, technology and innovation performance (MARBURGER, 2005; LIGHTFOOT,
28 2006). As yet there is no comprehensive national innovation survey undertaken in the
29 US which is comparable to the CIS in Europe: to date, our results are limited to only
30 one US region where a comparable data set has been established. However, this study

has shown that important differences and similarities can be uncovered through the use of innovation surveys. There are, of course, limitations of such surveys (see, for example, TETHER, 2001; SALAZAR and HOLBROOK, 2004), and any insights obtained should be corroborated by other research to ensure a validated evidence base for policy. Nonetheless, if a regionally-representative national innovation survey were to be implemented in the US that had compatibility with the approaches used by CIS and other non-European countries, this could greatly strengthen the knowledge base for innovation policymaking, both in the US and elsewhere.

Acknowledgements

We acknowledge the Georgia Manufacturing Extension Partnership, the US Economic Development Administration, and the Center for Paper and Business Industry Studies at Georgia Tech for their sponsorship of the Georgia Manufacturing Survey 2005. Stephen Roper is grateful to the Department of Trade and Industry, UK for permission to make use of the individual, anonymised returns from the UK 2005 Innovation Survey. Thanks are also due to the Generalitat de Catalunya/Fulbright for providing funding to support Andrea Fernández-Ribas under the grant FGENCAT2004/39702274 and to IDESCAT for providing the Catalan data. This paper was completed while Stephen Roper was a visiting researcher at the School of Public Policy and the Enterprise Innovation Institute, Georgia Institute of Technology, Fall 2006. Valuable comments were received from: participants in the Fourth British-Irish-Israel meeting of the Regional Science Association International, Ramat Gan, Israel, May 2007; participants in the British-Irish Regional Science Association Conference, Bangor, August 2007; James H Love, Aston; and, two anonymous

- Industry	0.6	0.7	0.7	0.8
- Higher education	0.3	0.4	0.3	0.3
- Other	0.2	0.1	0.0	0.1

Notes: GSP = Gross State/Regional Product; Working age employment rate is defined as the level of employment as a proportion of the working age population. Unemployment rates are defined relative to the labour force. Per capita income is Gross Value Added (GVA) or GSP per capita, with UK figures converted to US Dollars using the 2004 average exchange rate (£1=\$1.83). R&D spending figures are expressed as a proportion of GSP. GVA or GSP composition relates to 2003 for UK regions and 2005 for Georgia.

Sources: Georgia: population and labour market data, Mapstats, available at: <http://www.fedstats.gov/qf/states/13000.html>; regional GSP data from Table 3. GDP by State in Current Dollars, 2005. 		External Connectivity	
		<i>Low</i>	<i>High</i>
Internal Innovation Synergies	<i>Low</i>	Catalonia	Georgia
	<i>High</i>	Wales West Midlands	

For Peer Review Only

NOTES

1. In earlier studies we have considered the role of external factors in shaping comparative levels of innovation in Ireland and Israel (e.g. ROPER and FRENKEL, 2000), the UK and Germany (LOVE and ROPER, 2004) and Malaysia (SHAPIRA et al., 2006).
2. For example, the definition of product innovation as used in the UK CIS4 is: ‘a product innovation is the market introduction of a new good or service or a significantly improved good or service with respect to its capabilities, such as quality, user friendliness, software or subsystems’. The definition of process innovation is: ‘process innovation is the use of new or significantly improved methods for the production or supply of goods and services. The innovation must be new to your enterprise, but it does not need to be new to your industry’. The Spanish CIS definition of product and process innovation is comparable. Similar definitions are found in the 2005 Georgia Manufacturing Survey, where ‘A product innovation is the introduction of a new of significantly improved good or service. The innovation must be new to your facility but does not need to be new to your sector or market.’ The definition further excludes resale of goods purchased elsewhere or changes to colour or look. In the Georgia survey, ‘A process innovation is the implementation of a new or significantly improved production process or method of providing services. The innovation must be new to your facility but does not need to be new to your sector or market’.
3. The definition of wider innovation in the UK CIS4 is: ‘new or significantly amended forms of organisation, business structures or practices, aimed at step changes in internal efficiency of effectiveness or in approaching markets and

1
2 customers.' The Georgia survey asks about wider innovation changes through
3 probing organizational innovation ('new or significant changes in firm
4 structure, management methods, or information exchange systems') and
5 marketing innovation ('new or significant changes in your marketing methods
6 to increase the appeal of your goods or services or enter new markets').
7
8
9

- 10
11
12 4. UK CIS4 Questionnaire, question 13.
- 13
14 5. FALK (2006) argues that these error covariances also give an indication of the
15 links between innovation types. On this basis, we would interpret universally
16 positive complementarities in Georgia but find a more mixed pattern in the
17 two UK study regions.
18
19
20
21
22 6. Running the US and UK models restricting the sample to product and process
23 innovators provides an indication of the likely effect of different sampling
24 rules. In general the results are very similar to those presented here in terms of
25 the determinants of innovation of each type. In terms of complementarities
26 between types of innovation the results for the Georgian sample of product
27 and process innovators are also similar to those presented here. In the UK,
28 however, a different pattern of complementarities emerges suggesting that this
29 element of our comparative analysis is most sensitive in the UK case.
30
31
32
33
34
35
36
37
38
39 7. We find similar results when we run the model without including proxies for
40 complementarity. In this case, the correlation error between product and
41 process innovation is also negative and significant.
42
43
44
45 8. There is also the potential for some simultaneity between these variables and
46 firms' involvement in innovation itself. As the models suggest, however, any
47 such effect is far from uniform across different sorts of innovative activity and
48 the different study regions.

9. Some care is necessary in interpreting this policy impact given the well-
documented lack of consistency of such policy treatment effects (see
MADDALA, 1973; WOOLDRIDGE, 2002).
