International Convergence and Divergence of Material Input Structures: An Industry-Level Perspective

Abstract. This paper analyzes whether international material input structures have converged or diverged over time. Pooled variances for 25 industries were obtained from OECD input-output tables in constant prices for nine countries over the period 1971-1990. It is found that high-tech industries were mainly characterized by divergence of material input structures, whereas convergence was found for many low-tech, more mature industries. In line with studies on (labor) productivity growth rates, convergence of material input structures was prevalent in the 1970s, while divergence dominated in the 1980s.

Keywords: convergence, technology, specialization, input-output tables

Acknowledgement. We would like to thank Hartmut Kogelschatz for useful discussions on the statistical aspects of our study, and an anonymous referee for useful comments. An earlier version of this paper was presented at the International Conference on Input-Output and General Equilibrium: Data, Modeling and Policy Analysis, Brussels, September 2004, and at the 51st North American Meeting of the Regional Science Association International, Seattle, November 2004. Los thanks the Dutch Organization for Scientific Research NWO for financial support.

1. Introduction

Over the past couple of decades, globalization has become a keyword to describe the increased interrelatedness of nations with respect to trade and knowledge diffusion. The question we address in this note is how production processes of industrialized countries have changed as a consequence of international technological linkages. Using information from input-output tables, we analyze for each industry whether the structures of material inputs have converged, or not. In our definition, convergence takes place if the diversity (or, variability) of production technologies used across countries decreases.¹ In this respect, our convergence concept resembles the σ -convergence concept that is well known in studies of labor productivity and total factor productivity convergence (see, e.g. Bernard and Jones, 1996a).

In this paper, we will view changes in material input structures in the light of so-called “technology gap” models of growth (see, e.g., Fagerberg, 1987). In these models, two sources of change are highlighted: innovation and technological catch-up. Suppose a situation in which countries use identical material input structures in an industry. Any innovation will then induce a tendency to divergence, since one or a few national industries start adopting a different production technology that is perceived as an improvement over current practice. Later on, technology flows from technological leaders to followers (see, for instance, Coe & Helpman, 1995, and Verspagen, 1997) may induce technological catch-up, since latecomer countries might learn how to produce according to the technologies operated by the original

¹ To be more exact, we propose the reduction in the pooled variance of the material input coefficients of an industry as an indicator of convergence.

1
2
3 innovator(s). Ceteris paribus, material input structures will become more alike, or, in other
4
5 words, convergence will prevail.²
6
7

8 In the “real world”, many of such processes are simultaneously at work. Convergence
9
10 (divergence) occurs in a given time period if the effects of innovations by the leader are
11
12 smaller (larger) than the effects of catch-up through assimilation of diffused technology by
13
14 follower countries. Empirical analyses should provide answers to the question whether
15
16 convergence or divergence prevails.³ In this note, we use data from the OECD input-output
17
18 tables in constant prices for nine countries over the period 1971-1990, to compute our
19
20 convergence indicator for 25 industries.
21
22
23

24 The rest of the paper is organized as follows. The next section gives a more detailed
25
26 presentation of the basic technology gap model. The interactions between innovation and
27
28 technological catch-up are formalized and hypotheses about the typical industries for which
29
30 convergence resp. divergence of material input structures should prevail are formed. Section 3
31
32 presents the convergence indicator we propose. Section 4 discusses the data we use and
33
34 Section 5 deals with the results. Section 6 concludes.

41
42

43 **2. Technology gap models and convergence**

44
45
46
47

48 In traditional neoclassical economics (Solow, 1956), international differences in levels of
49
50 labor productivity were seen as transitory phenomena. Due to more attractive rates of return
51
52 to capital in low-productivity countries, investment rates were thought to be higher than in
53
54
55

56
57 ² The issue of convergence of technologies has been studied quite extensively, but almost exclusively on the
58
59 basis of trends in (labor or multifactor) productivity. Baumol (1986) is a classic contribution in this respect.

60 ³ Hoen (2002, Chapter 7) contains a first study, approaching the question from the perspective of trade theory,
however.

high-productivity countries. Ultimately, all countries will tend towards the same productivity level. If (exogenous) technological progress is taken into account (countries increase their productivity at a constant pace), convergence towards a steady-state gap of productivity levels will result, and growth rates will tend to equalize. Characteristic of these models is that technology is considered to be common to all countries. Differences in savings rates are considered the main cause of productivity growth differentials.

In the technology gap literature (Fagerberg, 1987, and Verspagen, 1991, are seminal studies, see e.g. Lim and McAleer, 2004, for a recent contribution), a different approach is proposed. High-productivity countries attain productivity growth by means of innovation. Since the knowledge pertaining to these innovations is assumed to disseminate slowly (or, at least, not instantaneously), low-productivity countries will initially lose ground, both in terms of productivity levels and growth rates. As soon as low-productivity countries start to “benefit” from their technological backwardness (for instance, by imitating high-productivity processes and products) catch-up can occur. Thus, the dynamics of the productivity gap between high-productivity countries and low-productivity countries is basically viewed as the outcome of two opposing forces: innovation by the leaders and assimilation by followers.

Let us for simplicity assume that there is just one productivity leader, country 0. The productivity followers are denoted by i ($i=1, \dots, n$). Then, the basic technology gap model is given by

$$\dot{y}_i - \dot{y}_0 = (\alpha_i - \alpha_0) + \beta_i \ln\left(\frac{y_i^{INI}}{y_0^{INI}}\right) \quad (1)$$

where dots denote growth rates and the superscript *INI* indicates a value in the initial period. y stands for productivity. The constants α_i ($i=0, \dots, n$) and β_i ($i=1, \dots, n$) denote country-specific abilities to innovate ($\alpha_i \geq 0$), and abilities to assimilate technology that originated with the

1
2
3 leader ($\beta_i \leq 0$), respectively.⁴ Countries that are unable to assimilate any technology will be
4
5 characterized by $\beta_i = 0$. The better country i is at assimilating (for instance due to a relatively
6
7 well-educated workforce), the more negative β_i will be.
8
9

10 For reasons of exposition, we assume that the leader's ability to innovate leads to a
11
12 stable, continuous flow of innovations that yields productivity growth at rate α_0 . Furthermore,
13
14 let us assume that follower countries cannot innovate at all by themselves ($\alpha_i = 0, i = 1, \dots, n$).
15
16 The equilibrium gaps for the productivity levels can now easily be found by setting the left
17
18 hand side of (1) equal to zero, that is -in equilibrium- the leader and the followers experience
19
20 identical productivity growth rates. Solving for the right hand side yields:
21
22
23
24
25
26
27

$$\frac{y_i^*}{y_0^*} = e^{(\alpha_0 / \beta_i)} \quad (2)$$

28
29
30
31
32
33 Thus, the equilibrium gaps for productivity levels are larger the faster innovations arrive in
34
35 the leader country and the smaller the rates of assimilation in follower countries are.
36
37
38

39 In many cases, productivity growth rates due to innovation as captured by α_0 are not
40
41 stable over time (see, e.g. Freeman & Soete, 1997). As a consequence, the equilibrium gap in
42
43 (2) and, therefore, actual productivity gaps will change over time. In the early stages of
44
45 product life cycles, productivity growth is often slow (α_0 small), due to the initially limited
46
47 scale at which innovative processes are used or innovated products are sold. Later on,
48
49 productivity growth picks up ($\alpha_0 \uparrow$), since the innovation has gained more popularity. Finally,
50
51 at the time processes and products reach the stage of maturity, the rate of innovation usually
52
53 goes down ($\alpha_0 \downarrow$), because opportunities for further improvement get fished out. If it is
54
55
56
57
58
59
60

⁴ Note that the ratio y_i^{INI} / y_0^{INI} in (1) is smaller than one.

1
2
3 assumed that the abilities to assimilate remain constant over time, the product life cycle can
4
5 be held responsible for changes in the distribution of gaps, as reflected in its variance.
6
7

8 In the traditional technology gap literature described so far, technologies are indicated
9
10 by productivity levels. In this study, we adopt a different perspective and use material input
11
12 structures as indicators of technology. If assimilation of leading technologies is predominant,
13
14 the industry-specific input structures will become more similar across countries. If innovation
15
16 is a more important factor, however, the contrary is true. The innovating industry will adopt
17
18 processes characterized by an input structure that deviates from what its foreign counterparts
19
20 do. As a consequence, input structures will become more heterogeneous.
21
22
23

24 In the literature on productivity convergence, scholars often investigate trends in
25
26 measures of dispersion, like the distribution's variance. If the dispersion in productivity or
27
28 income levels is decreasing, Bernard and Jones (1996a), Sala-i-Martin (1996) and Proietti
29
30 (2005), among others, denote this as σ -convergence. Several measures of dispersion have
31
32 been used in the literature, ranging from variances, standard deviations, and standard
33
34 deviations of transformed variables to weighted or unweighted coefficients of variation. In
35
36 this paper, we will focus on intertemporal comparisons of variances, because statistical theory
37
38 provides some natural yardsticks for assessing σ -convergence and σ -divergence for material
39
40 input structures.
41
42
43
44
45

46 In the technology gap model represented by (1), the variance of equilibrium gaps is
47
48 likely to increase (σ -divergence) during the transition from the early stage to the stage of
49
50 growth. High-productivity innovators will leap forward, while more backward countries will
51
52 stay further behind, which implies increased dispersion of productivity levels. During the
53
54 subsequent transition from the stage of growth to the maturity stage, however, the variance of
55
56 equilibrium gaps could well decrease (σ -convergence). Since adaptation to the equilibrium
57
58
59
60

distribution of gaps is generally considered as a slow process due to relatively modest abilities to assimilate, actual convergence and divergence processes are long-run phenomena.

In the next section, we will outline how we adapt a measure of σ -convergence in the literature on productivity convergence to study convergence of material input structures at the industry level.

3. Methodology

We base our analysis on input-output tables in constant prices. From these, we obtain the elements z_{ij} with the (domestic plus imported) intermediate deliveries from industry i to industry j ($i, j = 1, \dots, n$) and domestic gross outputs x_j in industry j . The elements $a_{ij} = z_{ij} / x_j$ denote the input coefficients of material input i per unit of output in industry j . Convergence (respectively divergence) of material input structures in industry j would imply that the j th columns of the matrices \mathbf{A} of input coefficients for the various countries become more (respectively less) similar. In line with the concept of σ -convergence for productivity levels outlined in the previous section, we analyze the changes in the similarity of the columns over time.⁵

Let the countries be denoted by the index $r = 1, \dots, m_t$ and note that the number of countries included in the sample differs over time. Then for each industry $j (= 1, \dots, n)$ at time t , we have

$$v_{ij}(t) = \frac{1}{m_t - 1} \sum_{r=1}^{m_t} [a_{ij}^r(t) - \bar{a}_{ij}(t)]^2, \text{ with } \bar{a}_{ij}(t) = \frac{1}{m_t} \sum_{r=1}^{m_t} a_{ij}^r(t) \quad (3)$$

This expression reflects the extent to which the input coefficient a_{ij} differs from the average value computed for the full set of countries. If the material input structures for industry j would be exactly identical across countries, $v_{ij}(t)$ would be zero. The use of any input I as a proportion of gross output is the same for each country.

If some elements a_{ij} vary across countries for industry j , a summary measure is needed to indicate the dissimilarity of international production technologies. The pooled variance, obtained by taking the average of the variances $v_{ij}(t)$, is the most straightforward candidate summary measure, i.e.

$$v_j(t) = \frac{1}{n} \sum_{i=1}^n v_{ij}(t) \quad (4)$$

If $v_j(t+1)$ is “substantially” smaller than $v_j(t)$, we will speak of convergence between period t and $t+1$. This resembles the conventional notion of σ -convergence, introduced in the previous section: from period t to period $t+1$, technologies have become more alike, most probably as a consequence of technology assimilation. Analogously, we will take a $v_j(t+1)$ that is “substantially” larger than $v_j(t)$ as an indication of divergence between t and $t+1$. As a yardstick, we use the corresponding F -statistic. For example (also other percentiles will be used),

- convergence took place if $v_j(t+1)/v_j(t) < F_{n(m_t-1)}^{n(m_{t+1}-1)}(0.05)$
- divergence took place if $v_j(t+1)/v_j(t) > F_{n(m_t-1)}^{n(m_{t+1}-1)}(0.95)$

⁵ Appendix B contains a simplified illustration of the calculations involved.

60

It should be stressed that we use the critical values of F -distributions only as a yardstick to distinguish between “large” and “small” differences. The application of an F -test to decide whether the differences are significantly different (in a statistical sense), would require unrealistically strong assumptions. That is, we would have to assume that the observations $a_{ij}^r(t)$ are normally distributed with mean $\mu_i(t)$ and a common variance $\sigma^2(t)$. Moreover, the observations would need to be independent across countries r and supplier industries i . In particular the assumption regarding independency seems to be violated in reality, because country-specific substitution effects, for example, may play a role. Nevertheless, comparisons to critical values of F -distributions give sensible indicators of the strength of convergence or divergence processes.

4. Data

We study the changes in material input structures in the way outlined in the previous section on the basis of a set of national input-output tables compiled by the OECD (OECD, 1995). It contains input-output tables for ten developed countries, using a 35-industry classification.⁶ For each country, three to five tables are available, roughly for the period 1968-1990. Unfortunately, the years for which tables are compiled do not exactly coincide. We decided to

⁶ These countries are Australia (AU), Canada (CA), Denmark (DK), France (FR), Germany (GE), Japan (JP), The Netherlands (NL), the United Kingdom (UK) and the United States of America (US). The OECD database also contains a single table for Italy. Since changes in tables are considered, we could not include Italy in our analysis.

1
2
3 follow the suggestion made in OECD (1995) to assign each table to a subperiod. Table 1
4 presents this grouping of tables.⁷
5
6
7
8
9

10 **INSERT TABLE 1**

11
12
13
14

15 Our analyses are based on the tables that contain all intermediate inputs, both domestically
16 produced and imported (in the OECD database these tables are encoded as “TIOK”). This
17 choice is in accordance with the idea that material input structures should resemble
18 technologies of industries. Mere changes in the mix of domestically produced and imported
19 inputs should not affect these representations, unless domestically produced inputs from
20 supplying industry i would be different from imported inputs from industry i . Since the
21 OECD constructed the tables according to an internationally harmonized industry
22 classification, risks that substantial systematic differences affect the results are strongly
23 reduced.
24
25
26
27
28
29
30
31
32
33
34

35
36 The interindustry transactions recorded in the tables for any country are denominated
37 in the national currency. Further, the tables are expressed in constant prices. As a
38 consequence, information on (physical) quantities of inputs (which represent the material
39 input structures we are interested in) is thus approximated as well as possible, because
40 inflation and changes in exchange rates do not contaminate the coefficients.⁸
41
42
43
44
45
46
47

48 Since national statistical agencies did not construct their national input-output tables
49 in exactly the same way, the OECD tables are not fully comparable. Some industries are not
50 contained as separate entities in tables for some countries, whereas they do for others (see
51
52
53
54

55
56 ⁷ We decided to adopt the grouping suggested by OECD (1995, p. 7), except for one table. That is, we
57 included UK(1979) in the third subperiod, whereas OECD (1995) assigned it to the second subperiod. Our
58 grouping yields less variance within groups with respect to timing.
59
60

1
2
3 OECD, 1995, p. 12). To make the tables as comparable as possible we had to aggregate a
4
5 limited number of industries. The aggregation scheme is included in Appendix A. We finally
6
7 computed the pooled variances for 25 industries, each of them based on material input
8
9 coefficients vectors that consist of 25 elements.
10
11
12
13
14
15
16

17 **5. Results**

18
19
20
21
22 Applying equations (3) and (4) to the OECD (1995) tables and using the specified criteria for
23
24 convergence and divergence, yields the results documented in Table 2. The rightmost
25
26 columns refer to trends over the entire period of analysis, i.e. 1971-1990. An overwhelming
27
28 majority of industries (i.e., 19 out of 25) has experienced either convergence or divergence of
29
30 material input structures, as measured by the yardstick of the 10th, respectively the 90th,
31
32 percentiles of the appropriate *F*-distributions.
33
34
35
36
37
38

39 **INSERT TABLE 2**

40
41
42
43 In particular, many manufacturing industries that are widely considered as “low-tech” – such
44
45 as textiles (4), wood products (5), paper (6), petroleum (8), and basic metals (11) – appear to
46
47 have converged. Convergence is also found for primary industries – agriculture (1) and
48
49 mining (2) – and for a limited number of services industries. This is in line with the prediction
50
51 from the technology gap literature briefly discussed in Section 2, based on the argument that
52
53 innovation by technological leaders has slowed down in these “mature” industries. The
54
55 technology gap will thus be narrowed if the ability of follower countries to assimilate diffused
56
57
58
59
60

⁸ It should be mentioned that the base years used for deflation are not identical for all countries, which may

1
2
3 technology has not decreased. This would yield clearcut tendencies towards convergence of
4
5 the material input structures.
6
7

8 The results for most high-tech and medium-tech manufacturing industries support this
9
10 explanation. Most industries that belong to this group – such as chemicals (7), plastics (9),
11
12 machinery (13), ships (14), and transport equipment, (15) – show either divergence or no
13
14 discernible tendency. An increase of the leaders' innovation rates will widen the technology
15
16 gap inducing divergence, if abilities to assimilate knowledge remain unaltered. A similar
17
18 argument seems to hold for business services (24), an industry characterized by a high degree
19
20 of organizational innovation.
21
22
23

24 It should be noted, however, that we are not able to explain the findings for every
25
26 industry. For example, the low-tech industries glass and stone (10) and metal products (12)
27
28 show divergence, whereas the high-tech industry instruments (16) is found to have
29
30 experienced convergent tendencies. Specialization might play a role in this (for example,
31
32 metal products is characterized by a high degree of product differentiation which may be
33
34 taken as an indication of specialization).
35
36
37

38 Several generations of trade theories predict that countries will specialize in different
39
40 production processes (Jones, 1956, Krugman, 1981, Grossman, 1992). The OECD input-
41
42 output tables, however, are rather aggregated, whereas specialization typically takes place at
43
44 the more detailed level of “subindustries”. Each of these can be characterized by its own
45
46 material input structure. Once such subindustries are aggregated into an industry, the
47
48 subindustries in which a country is specialized will most strongly influence the structure of
49
50 the (aggregate) industry. Changes in the input structure of an industry may therefore also be
51
52 partly due to changes in the mix of its subindustries, as caused by changes in specialization
53
54 patterns. The problem, however, is that an increase in specialization may lead to convergence
55
56
57
58
59
60

affect our results.

1
2
3 in one case and to divergence in an other. Therefore, although specialization may play some
4
5 role, it cannot be used as a factor to explain the observed patterns of convergence/divergence,
6
7 because the direction of its effect cannot be ascertained.
8
9

10 Looking at the results for shorter subperiods, it is not surprising that a far more
11
12 heterogeneous pattern is found than for the results over the entire period. The bottom row
13
14 shows that an initial tendency towards convergence was gradually overturned. In the late
15
16 1980s, divergence rather than convergence of material input structures was found most often.
17
18 This result is in line with studies that focus on convergence and divergence of labor
19
20 productivity levels (see, e.g., Bernard & Jones, 1996a, 1996b, and Los & Timmer, 2005).
21
22 From the perspective of single industries, only few show a more or less persistent
23
24 development, such as agriculture (1), ships (14), other manufacturing (17), utilities (18) and
25
26 government services (25). For the other industries, it is remarkable that subperiods with
27
28 convergence are often followed by subperiods of divergence (and vice versa). These
29
30 counteracting short-run effects certainly call for further analysis at a more detailed industry
31
32 level. At the present level, they seem to have blurred the long-run tendencies indicated by the
33
34 results for the entire period.
35
36
37
38
39
40
41
42
43
44

45 **6. Conclusions**

46
47
48
49
50 This note explored opportunities to incorporate changing patterns of material input structures
51
52 into analyses of international convergence and divergence. For the period 1971-1990, the
53
54 analysis based on pooled variances of input coefficients revealed that high-tech industries
55
56 were mainly characterized by divergence of material input structures, whereas convergence
57
58 was found for many low-tech, more mature industries. These results confirm hypotheses
59
60

1
2
3 derived from the literature on technology gap models. As is in line with studies that focus on
4 convergence and divergence of (labor) productivity growth rates, convergence of material
5 input structures was prevalent in the 1970s, while divergence dominated in the 1980s.

Appendix A: Industry classification for analyses based on OECD (1995) data

No.	Description	OECD IO code	ISIC Rev. 2 code
1.	Agriculture, forestry and fishery	1	1
2.	Mining and quarrying	2	2
3.	Food, beverage and tobacco	3	31
4.	Textiles, apparel and leather	4	32
5.	Wood products and furniture	5	33
6.	Paper, paper products and printing	6	34
7.	Chemicals, including drugs and medicines	7+8	351+352
8.	Petroleum and coal products	9	353+354
9.	Rubber and plastic products	10	355+356
10.	Non-metallic mineral products	11	36
11.	Basic metals	12+13	37
12.	Metal products	14	381
13.	Machinery, including electronics	15+16+17+18	382+383
14.	Shipbuilding and repairing	19	3841
15.	Other transport equipment	20+21+22	384-3841
16.	Professional goods	23	385
17.	Other manufacturing	24	39
18.	Electricity, gas and water	25	4
19.	Construction	26	5
20.	Wholesale and retail trade	27	61+62
21.	Restaurants and hotels	28	63
22.	Transport and storage services	29	71
23.	Communication services	30	72
24.	Financial and business services	31+32	8
25.	Community, social and government services	33+34+35	9

Appendix B: Illustration of computations

Consider the following simplified tables with input coefficients, for the hypothetical countries A and B ($m_i=2$, see equation (3)), for $t=0$ and $t=1$.

Country A, $t=0$

	1	2	3
1	0.2	0.1	0.1
2	0.2	0.2	0.1
3	0.2	0.1	0.3

Country B, $t=0$

	1	2	3
1	0.3	0.2	0.1
2	0.2	0.1	0.1
3	0.1	0.1	0.2

Country A, $t=1$

	1	2	3
1	0.2	0.1	0.1
2	0.2	0.2	0.1
3	0.2	0.1	0.3

Country B, $t=1$

	1	2	3
1	0.2	0.3	0.1
2	0.2	0.1	0.1
3	0.1	0.1	0.2

Suppose one is interested in the convergence or divergence of material input coefficients of industry 1 ($j=1$), in this small set of countries. According to equation (3), we first compute

$\bar{a}_{11}(0) = \frac{1}{2}(0.2 + 0.3) = 0.25$, and $\bar{a}_{11}(1) = \frac{1}{2}(0.2 + 0.2) = 0.2$. In a similar vein, we find $\bar{a}_{21}(0) = 0.2$, $\bar{a}_{21}(1) = 0.2$, $\bar{a}_{31}(0) = 0.15$, and $\bar{a}_{31}(1) = 0.15$. These average input coefficients for the first column and the input coefficients themselves yield $v_{11}(0) = (0.2-0.25)^2 + (0.3-0.25)^2 = 0.005$ and $v_{11}(1) = (0.2-0.2)^2 + (0.2-0.2)^2 = 0$. Similarly, we find $v_{21}(0) = 0$, $v_{21}(1) = 0$, $v_{31}(0) = 0.005$ and $v_{31}(1) = 0.005$.

The above-mentioned cell-specific variances can now be used to compute the pooled variances expressed in equation (4): $v_1(0) = (0.005+0+0.005)/3 = 0.0033$ and $v_1(1) = (0+0+0.005)/3 = 0.0017$. In this specific case, the pooled variance for industry 1's material inputs has decreased. To get insight into the strength of this process, we compute the ration between $v_1(1)$ and $v_1(0)$, which is 0.50 and compare this value to $F_2^2(0.05) = 0.053$. The observed ratio is much larger, so the tendency towards convergence would not be sufficient to warrant inclusion as C* in Table 2.

Table 1: Availability and grouping of OECD tables

“1971”	AU(68)	CA(71)	DK(72)	FR(72)		JP(70)	NL(72)	UK(68)	US(72)
“1976”	AU(74)	CA(76)	DK(77)	FR(77)	GE(78)	JP(75)	NL(77)		US(77)
“1980”		CA(81)	DK(80)	FR(80)		JP(80)	NL(81)	UK(79)	US(82)
“1985”	AU(86)	CA(86)	DK(85)	FR(85)	GE(86)	JP(85)	NL(86)	UK(84)	US(85)
“1990”	AU(89)	CA(90)	DK(90)	FR(90)	GE(90)	JP(90)		UK(90)	US(90)

Note: First column contains labels for subperiods. Values between parentheses refer to years.

For Peer Review

Table 2. Convergence and divergence of sectoral input structures in the OECD, 1971-1990.

Total	C:	11		11		10		4		12
	D:	2		4		5		8		7

Notes: The numbers represent the ratios of pooled variances between the final year and the initial year of the periods indicated in the column headings, for the industries in the corresponding rows (see equation (4)).

The letter C indicates 'significant' convergence. In this case *, **, and *** show that the observed ratio is smaller than the 10th, 5th, or 1st percentile, respectively, of the corresponding F -distribution. The letter D indicates 'significant' divergence. In this case, *, **, and *** show that the observed ratio is larger than the 90th, 95th, or 99th percentile, respectively, of the corresponding F -distribution.
