## Visible minorities and 'White' – 'non-White' Conjugal Unions in Canadian Large cities

**Abstract:** The study investigates assortative mating patterns with respect to race (visible minority status) in Canada. Using the 2001 Census data, the article analyses the occurrence of White/non-White unions in Montreal, Toronto, and Vancouver. Log-linear models indicate that the relative levels of interracial relationships vary across racial groups, immigration status, and place of residence. First, the highest odds of cohabiting or marrying a White person are found among Blacks. Whereas the high level of racial exogamy of Blacks is observed in all metropolitan areas under study, the relative position of other groups varies. Second, the highest levels of racial exogamy are found among couples comprising an immigrant and a non-immigrant but this effect varies across racial groups. Third, our hypothesis that residents of Montreal (Quebec) will interpartner less was confirmed only for unions between two native born Canadians. Finally, we found that French Canadians are not more inclusive of their linguistic counterparts than Anglophones.

**Key words:** racial intermarriage, visible minority, Canada, homogamy, assortative mating, interracial

**AUTHORS:**

**ACKNOWLEDGEMENTS:**

The analysis is based on research carried out in the Quebec Inter-University Centre for Social Statistics, which provides researchers with access to detailed longitudinal survey data collected by Statistics Canada. The opinions expressed here do not represent the views of Statistics Canada. Support for this research was provided by the Social Science and Humanities Research Council and the McGill Canada Research Chair on Social Statistics and Family Change.

1  
2  
3 Levels of interracial, interethnic, or intercultural marriage are commonly used to  
4 describe the openness of societies and the degree of equality among people of  
5 various ethnic, racial, or cultural origins. The extent to which members of different  
6 racial and ethnic groups marry each other demonstrates group boundaries, social  
7 distance, and acceptance of minorities (Qian and Lichter, 2007, Tzeng, 2000,  
8 Kalbach, 2002). Some authors even argue that ethnic/racial intermarriage is the  
9 single best indicator of minority assimilation (Gordon, 1964, Lee and Boyd, 2008)  
10 or that mixed unions are ‘an engine of social change’ (Milan and Hamm, 2004).

22 Most previous research on interracial mating analysed the situation in the  
23 United States (Fu et al., 2001, Qian and Lichter, 2001, Qian, 1997, Qian and Cobas,  
24 2004, Harris and Ono, 2005, Model and Fisher, 2002). In contrast, we know  
25 relatively little about these patterns in Canada. Past Canadian studies focused  
26 primarily on intermarriage in terms of ancestry, for example intermarriage among  
27 people of British, Irish, or Ukrainian origin (Kalbach, 1983, Kalbach, 2002, Richard,  
28 1991), or on intermarriage in terms of the place of birth (Canadian-born versus  
29 foreign-born; Tzeng, 2000). Lee and Boyd’s (2008) recent work is an exception in  
30 that they focus on interracial couples; they, however, restrict their analysis solely to  
31 unions involving Canadians of an Asian origin.

46 The lack of studies on interracial couples in Canada is surprising given the  
47 fact that Canada is an immigration country and that an increasing number of  
48 immigrants are coming from non-European countries. In 2001, 18 per cent of  
49 Canada’s population was foreign-born (Statistics Canada, 2003b) – a percentage 1.6  
50 times higher than that in the United States (Camarota, 2002) and one of the highest

2  
3 in Canadian history. At the turn of the century, 73 per cent of immigrants who came  
4  
5 to Canada in the 1990s were classified as belonging to a visible minority group  
6  
7  
8 (Statistics Canada, 2003a).  
9

10 The absence of research on racially mixed conjugal couples can be partly  
11 explained by the lack of appropriate data as Canadian statistics do not traditionally  
12 collect information on race but only on ethnic origin, immigration status or place of  
13 birth. Data on the ethnic origin are unfortunately of limited use, given that a large  
14 proportion of respondents declare multiple ancestries or use the category 'Canadian'  
15 (Pryor et al., 1992). However, despite the fact that Canadian statistics do not work  
16 with the concept of race, more recent censuses and surveys introduced the concept of  
17 'visible minority' that designates 'persons, other than Aboriginals, who are non-  
18 Caucasian in race or non-white in skin colour' (Department of Justice Canada,  
19 1995).

34 In this paper, we use the opportunity offered by the 2001 micro-detailed  
35 Census data to analyse unions between visible minorities and non-minority  
36 individuals (i.e. 'White' – 'non-White' unions). Furthermore, we consider the  
37 importance of mother tongue as linguistic issues play a prominent role in Canada,  
38 especially in the French province of Quebec. Our definition of race and interracial  
39 unions is based on self-declared status, i.e. we consider a union to be interracial if  
40 one of the partners reported a non-minority status and the other declared a visible  
41 minority status. We focus on the simple question of how common these unions are  
42 and which visible minorities are more likely to enter into a union with Whites. Our  
43 effort should not be understood as an attempt to build a comprehensive picture of  
44

1  
2  
3 racial assortative mating in Canada. It should rather be viewed as a step towards a  
4  
5 better understanding of interracial unions.  
6  
7

8 Specifically, we are interested in variations across three Canada's gateway  
9  
10 cities: Montreal, Toronto, and Vancouver. These metropolitan areas were selected  
11  
12 for three reasons. First, about 75 per cent of immigrants and 73 per cent of visible  
13  
14 minorities reside in these areas (Hou and Picot, 2004), and their minority  
15  
16 populations are large enough to make the analysis possible. Second, given the high  
17  
18 concentration of visible minorities in these three metropolitan areas, our analysis  
19  
20 provides a rather accurate picture of interracial unions in Canada as a whole. Finally,  
21  
22 using metropolitan areas as a unit of analysis will help us to avoid making untenable  
23  
24 assumptions about the existence of one Canada-wide marriage market (Harris and  
25  
26 Ono, 2005).

### 34 **1. Interracial conjugal unions, social boundary, and social integration**

35  
36 Research on assortative mating, i.e. how much spouses resemble each other, has a  
37  
38 long tradition in social sciences as the levels of intermarriage are often used to  
39  
40 characterize the patterns of social stratification, openness of the society, and  
41  
42 boundaries of social groups. Homogamy (endogamy) refers to couples who share  
43  
44 similar characteristics. Heterogamy (intermarriage, exogamy) describes unions  
45  
46 between individuals who are dissimilar in the given trait. There is a vast body of  
47  
48 research that investigates homogamy with respect to religion (Johnson, 1980),  
49  
50 immigration status (Tzeng, 2000, Meng and Gregory, 2005), education (Mare, 1991,  
51  
52 Hamplova, 2009, Hamplova and Le Bourdais, 2008), occupation (Smits et al., 1999),  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 race (Harris and Ono, 2005), ethnicity (Kalbach, 2002), or a combination of these  
4  
5 characteristics (Qian and Lichter, 2007, Blossfeld and Timm, 2003).  
6  
7

8 In immigration countries like Canada, Australia or the United States,  
9  
10 analyses of interracial/interethnic marriage occupy a special position within this  
11  
12 tradition because racial intermarriage has wide implications regarding the integration  
13  
14 of ethnic and racial minorities (Qian and Lichter, 2007, Alba and Nee, 2003).  
15  
16 Intermarriage is often considered to be both a sign of minorities' assimilation and an  
17  
18 engine of further integration. The former process refers to the fact that intermarriage  
19  
20 is a visible manifestation of inter-ethnic contacts. It signals that individuals of  
21  
22 different backgrounds no longer perceive social and cultural differences to be  
23  
24 significant enough to prevent them from forming a long-term intimate union  
25  
26 (Gordon, 1964, see Alba and Nee 2003). The latter process views intermarriage not  
27  
28 as a sign of already completed integration but rather as a vehicle leading towards  
29  
30 assimilation. Through intermarriage, minorities are expected to acquire customs of  
31  
32 the mainstream culture that are important for achieving success in the host society  
33  
34 (Meng and Gregory, 2005).  
35  
36  
37  
38  
39  
40

41 Note, however, that although intermarriage is important for understanding  
42  
43 interracial relations, it should not be unquestionably taken as a sign of full  
44  
45 integration. Song (2009) reminds us that high levels of intermarriage are not  
46  
47 necessarily accompanied by integration in all domains of life. For example, Black  
48  
49 Britons highly intermarry with Whites but a significant portion of them are not  
50  
51 economically integrated. Moreover, as Song argues intermarriage does not  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 automatically produce the loss of ethnic identity. On the contrary, racial awareness  
4  
5 might be heightened by direct contact with a member of another racial group.  
6  
7  
8  
9

## 10 **2. Interracial conjugal unions across Canadian gateway cities**

11  
12 Before we elaborate hypotheses about factors that are likely to be associated with  
13 racial exogamy, we briefly summarize the history of Canadian immigration. The  
14 racial and ethnic composition of the Canadian population is shaped by the fact that,  
15 aside from the Aboriginals, everyone in Canada is an immigrant or an offspring of  
16 immigrants. The country was established by the French and British and these two  
17 groups represented around 90 percent of the population up to the end of the 19<sup>th</sup>  
18 century (Driedger, 1996). We must also note that Blacks lived in Canada from the  
19 very beginning of the European settlement. Yet, their history significantly differs  
20 from that of their U.S. counterparts. Slavery was nearly non-existent in Canada and  
21 most Blacks came to the country voluntarily, often escaping from the United States  
22 and West Indies (Tulloch, 1975, Hepburn, 2007, Winks, 1971).  
23

34  
35  
36  
37  
38

39 Throughout the first half of the 20<sup>th</sup> century, the European immigration  
40 became more diverse but non-European immigration was highly restricted. Most of  
41 the existing restrictions were lifted in the early 1960s and, in 1967, a point-based  
42 “colour-blind” system focusing on the immigrants’ human capital was introduced  
43 (Kelley, 1998). Consequently, the proportion of non-White immigrants increased  
44 dramatically.

## 2.1. Hypotheses

In this section, we formulate four hypotheses about factors that might be associated with racial intermarriage in Canada. First, past research has shown that the rates of interracial unions vary across racial groups and that some minorities partner outside their own circle more easily than others.

Accordingly, we expect that various visible minority groups in Canada have different tendencies to partner with Whites. However, the relative distance separating the groups is probably not the same as it is in other countries. For example, Blacks – who have the lowest rates of intermarriage in the United States (Harris and Ono, 2005, Qian and Lichter, 2001) – have had a different historical experience in Canada. Simple descriptive statistics indeed suggest that a relatively high proportion of them lives in mixed unions (Milan and Hamm, 2004).

Second, we expect to find significant variations across the three metropolitan areas (Montreal, Toronto, and Vancouver). The frequency of interracial conjugal unions in any given city is likely to be strongly influenced by the size of the particular visible minority populations (Qian and Lichter, 2007, Davison and Widman, 2002, Qian and Lichter, 2001). To understand the effect of the population size on interracial unions, we need to distinguish between its ‘numerical’ and ‘substantial’ effect. While the latter speaks about different propensity to partner outside of one’s own group, the former points to the fact that a larger group has larger marginal totals (because of group size, the frequencies in the given rows and columns are large). Consequently, the cell referring to homogamous couples will be larger for more numerous groups even if there is no association between the row and

1  
2  
3 column variables (Powers and Xie, 2000). In other words, as population size grows,  
4  
5 the number (and proportion) of homogamous couples increases even if the pairing  
6  
7 with respect to race is completely random.  
8  
9

10 Reflecting this statistical property, we expect that the observed *percentage* of  
11  
12 White/non-White unions will be smaller for larger groups and in the metropolitan  
13  
14 areas with the larger visible minority population. However, the relationship between  
15  
16 the size of the population and racial exogamy may not hold once we control for the  
17  
18 group size. In fact, the association between the size of the minority population and  
19  
20 exogamy could be reversed once a multivariate method is applied (Qian and Lichter,  
21  
22 2007).  
23  
24  
25  
26

27 Third, we expect that Montreal – as a part of the French province of  
28  
29 Quebec – is likely to exhibit weaker predisposition towards interracial partnerships.  
30  
31 Traditionally, French Canadians have displayed lower levels of marital exogamy  
32  
33 (Hurd, 1964, Kalbach, 2002, Richard, 1991), and recent surveys show that  
34  
35 Quebecers still hold less positive attitudes towards immigrants and racial  
36  
37 intermarriage (Girard, 2008). In contrast, we predict that Vancouver will display the  
38  
39 highest tendency towards interracial pairing, as the West has been multicultural and  
40  
41 multilingual throughout its past and no single ethnic group ever had a majority  
42  
43 (Driedger, 1996).  
44  
45  
46  
47

48 However, Montreal's weaker tendency towards interracial pairing could be  
49  
50 attenuated by other factors. Quebec has specific immigration policies that might  
51  
52 affect minorities' integration. For example, Quebec is the only province in Canada  
53  
54 that has the right to pre-select immigrants best suited for living in its francophone  
55  
56  
57  
58  
59  
60

1  
2  
3 society. Moreover, this province rejected Canadian ‘multiculturalism’ (Nugent,  
4 2006) and adopted a policy of ‘inter-culturalism’ whose goal is to integrate  
5 minorities into the francophone ‘nation québécoise’ (Labelle et al., 1995). Given the  
6 fact that the linguistic issues are given a prominent – and arguably even increasing –  
7 role in defining the cultural boundaries and delimiting the ‘nation québécoise’ (Elliot  
8 and Fleras, 1992), interracial/interethnic barriers might be weakened among French  
9 speaking minorities.  
10  
11  
12  
13  
14  
15  
16  
17  
18  
19

20 Finally, we acknowledge that immigration status and differences between  
21 Canadian-born and foreign-born visible minorities constitute another important  
22 factor that needs to be taken into consideration. The immigration status of  
23 individuals is likely to influence both the levels and the patterns of interracial  
24 assortative mating. The former points to the fact that immigrants tend to intermarry  
25 to a different extent than native born visible minorities (Qian and Lichter, 2007,  
26 Qian and Lichter, 2001). The latter suggests that the relative proximity of racial  
27 groups might vary depending upon whether the individual is an immigrant.  
28

### 41 **3. Data and method**

42  
43 To compare White/non-White unions in Montreal, Toronto, and Vancouver, we used  
44 the 20 per cent analytic sample from the 2001 Census available in Research Data  
45 Centers (RDC). As Statistics Canada did not provide a family file, we used the  
46 individual-level data and linked couples together. In total, we retrieved information  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 on 97.6 per cent of respondents who were identified as opposite-sex spouses or  
4  
5  
6 cohabitants<sup>1</sup>.  
7

8 Only couples living in Montreal, Toronto, and Vancouver and couples where  
9  
10 none of the partners declared multiple visible minority status, 'minority n.i.e' (not  
11  
12 included elsewhere) or aboriginal status, were selected for the analysis. Individuals  
13  
14 with multiple minority statuses were left out as it is not clear what 'intermarriage'  
15  
16 stands for in their case. Aboriginals were not included for three reasons. First, they  
17  
18 are not classified among visible minorities (Department of Justice Canada, 1995).  
19  
20 Second, we analyse variation across immigration status, which does not apply to the  
21  
22 First Nations. Finally, they often live on reserves, which might restrict their access to  
23  
24 partners from other racial groups. Furthermore, we selected only individuals who  
25  
26 were born in Canada or immigrated before age seventeen. Those who migrated at a  
27  
28 later age might have formed a union before they arrived to Canada.  
29  
30  
31  
32  
33

34 In total, information on 235,457 couples is available (109,245 couples in  
35  
36 Montreal, 85,848 in Toronto, and 40,364 in Vancouver). After reporting descriptive  
37  
38 statistics and distribution of interracial couples, we turn our attention to log-linear  
39  
40 models. This method distinguishes between patterns that result from the marginal  
41  
42 distributions of the male and female characteristics (i.e. the relative size of their  
43  
44 racial group), and those that reflect the association between the partners' traits  
45  
46 (Mare, 1991, Powers and Xie, 2000).  
47  
48  
49

---

56  
57 <sup>1</sup> Our sample does not include higher order couples in multiple family households.  
58  
59  
60

## 4. Results

### 4.1. Descriptive statistics

The 2001 Census distinguishes ten visible minority groups: Chinese, South Asians<sup>2</sup>, Blacks<sup>3</sup>, Filipinos, Latin Americans<sup>4</sup>, South East Asians<sup>5</sup>, Arabs<sup>6</sup>, West Asians<sup>7</sup>, Koreans, and Japanese (sorted by the size of the population in descending order). Table 1 reports the percentage of the total population of Montreal, Toronto and Vancouver that each group represents. The table shows that Vancouver has the highest proportion of visible minorities (35 per cent of Vancouver men and 36 per cent of Vancouver women), followed closely by Toronto (34 per cent of men and 35 per cent of women). In contrast, Montreal has the smallest visible minority population (13 per cent of men and women). In Vancouver, over 80 per cent of visible minorities are Asians. In contrast, Asians represent only approximately 35 per cent of the non-White population in Montreal and around 65 per cent in Toronto.

<Table 1 >

The left part of Table 2 shows the total percentage of visible minority individuals who live with a partner from a different group (all interracial couples).

---

<sup>2</sup> East Indians, Bangladeshis, Pakistanis etc.

<sup>3</sup> Jamaicans, Blacks, Somalis, etc.

<sup>4</sup> Spanish, Latin/Central/South Americans, Mexicans, etc.

<sup>5</sup> Vietnamese, Cambodians, etc.

<sup>6</sup> Arabs, Lebanese, Iraqis, etc.

<sup>7</sup> Iranians, Afghans, West Asians.

1  
2  
3 The middle part gives the same statistics, after excluding all couples comprising an  
4 immigrant who arrived to Canada after age 16. Finally, the right part of the table  
5 reports the percentage of White/non-White couples among this restricted sample.  
6  
7  
8  
9

10  
11  
12 <Table 2>  
13  
14  
15

16  
17 The expectation that the percentage of interracial couples is inversely related  
18 to the size of the minority population is confirmed only for men. The highest  
19 proportion of inter-partnered men is indeed in Montreal which has the smallest non-  
20 White population. In this city, around 16 per cent of married or cohabiting non-  
21 White men live with a spouse of a different racial status. In contrast, only  
22 approximately 9 per cent of their counterparts in Toronto and Vancouver are in  
23 interracial unions. The inverse relationship between the size of population and the  
24 proportion of men in interracial couples is more evident if we leave out immigrants  
25 who arrived to Canada after age sixteen (48 per cent in interracial unions in  
26 Montreal, 40 per cent in Toronto, 38 per cent in Vancouver). However, the same  
27 conclusion cannot be drawn for women as the percentage of those living in  
28 interracial unions is nearly as high in Vancouver as it is in Montreal.  
29

35  
36  
37  
38  
39  
40  
41  
42  
43  
44

45 We already argued that percentages are not a very good measure of  
46 association because they are partly determined by the number of men and women in  
47 the given racial category. Therefore, we turn to log-linear models to estimate the  
48 number of exogamous unions, net of the population size.

#### 4.2. Log-linear models

To estimate the log-linear models, the data were cross-classified into a five-way table<sup>8</sup>: *man's visible minority status* x *woman's visible minority status* x *man's immigration status* x *woman's immigration status*<sup>9</sup> x *metropolitan area*. Model specification and corresponding fit statistics are reported in Table 3. Model selection is based on BIC statistic.. Generally, a negative BIC signifies that the model replicates the pattern in the table adequately and the more negative BIC is, the better the fit of the model (Raftery, 1995). Below, we briefly describe how we selected the model that will be used for interpretation.

Model 1 in Table 3 serves as a baseline for evaluation. It controls for the number of men and women in the racial categories in the selected metropolitan areas and their immigration status, and it includes dummies controlling for originally empty cells (see footnote 10). Furthermore, this model saturates the overall interaction between man's and woman's race, i.e. posits that there is some general

---

<sup>8</sup> The minority status is classified into eleven categories (visible minorities + 'White'). *Immigration* differentiates immigrants from non-immigrants. *City* designates Montreal, Toronto, or Vancouver. This cross-classification produced a table with 1,452 cells. As some cells in the table were empty, we imputed them with a constant (0.5). None of these empty cells are among the cells with the minority/White couples.

<sup>9</sup> Refers to immigrants who arrived to Canada before age 17.

1  
2  
3 resemblance between men's and women's race but holds this resemblance constant  
4  
5 across cities and immigration status.<sup>10</sup>  
6  
7

8 Model 2 tests whether the *overall* tendency towards racial intermarriage  
9  
10 differs across these three cities. Its fit statistics confirm this expectation (BIC  
11  
12 dropped by 980.3). Therefore, we must conclude that the odds of crossing a racial  
13  
14 barrier significantly differ depending on whether a couple lives in Toronto,  
15  
16 Montreal, or Vancouver. Model 3 considers the effect of the immigration status of  
17  
18 the couple. Another dramatic decrease in the BIC confirms that the relative  
19  
20 similarity of the partners' immigration status is highly significant (BIC: -600.0  
21  
22 versus -12,414.7). Model 4 tests whether the effect of being an immigrant varies  
23  
24 across cities. As the BIC statistic drops again (from -12,414.7 to -14,146.9), we must  
25  
26 conclude that the gap between immigrants and non-immigrants depends on whether  
27  
28 they live in Montreal, Toronto, or Vancouver.  
29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40

<Table 3 >

41 All previous models measured the overall tendency toward racial  
42  
43 intermarriage. In other words, we did not consider any potential differences in  
44  
45 mating behaviour across visible minority groups. However, as previous research  
46  
47 suggests, this expectation is not realistic. Therefore, the following models use ten  
48  
49  
50

---

51  
52  
53 <sup>10</sup> The strategy to include the overall interaction is appropriate if our main interest is to show  
54  
55 differences in the association as it allows us to focus on similarity or dissimilarity. This will also help  
56  
57 us to take care of associations that are not the focus of our interest.  
58  
59  
60

1  
2  
3 group-specific parameters instead of one single overall parameter. This will allow us  
4  
5 to estimate odds of intermarriage for each minority group separately.  
6  
7

8 Models 5 to 7 are direct replications of Models 2 to 4 but account for  
9  
10 differences across visible minority groups. Again, we started by testing differences  
11  
12 across cities and then continued with differences across immigration statuses. As the  
13  
14 modeling strategy and conclusions derived above also hold for this part of the  
15  
16 analysis (see Table 3), we do not go through detailed comments. It suffices to say  
17  
18 that the effect of nativity and place of residence is not the same for all visible  
19  
20 minority groups.  
21  
22  
23

24 In the last step, we checked whether all the higher order interaction terms are  
25  
26 still significant. As the odds of intermarriage for couples formed by two immigrants  
27  
28 did not significantly vary across cities, this three-way interaction was taken out.  
29  
30 However, the odds for couples of two native born Canadians remained different in  
31  
32 each metropolitan area. This model (Model 8) shows the best fit of all models that  
33  
34 measure group-specific propensity towards marrying outside one's own group.  
35  
36  
37

38 Four conclusions can be drawn from the fit statistics of the log-linear models  
39  
40 presented here. First, residents of Montreal, Toronto, and Vancouver differ with  
41  
42 respect to the odds of living in interracial unions. Second, different visible minority  
43  
44 groups face different odds of forming a union with a White partner. Third, group-  
45  
46 specific odds of intermarriage with Whites vary across the cities. Fourth,  
47  
48 immigration status matters but its effect is not the same for all minorities and in all  
49  
50 metropolitan areas.  
51  
52  
53

55  
56  
57  
58  
59  
60

#### 4.3. Interpretation of parameters from Model 8

Table 3 informs us about factors that are significant but it does not tell us anything about the strength and the direction of the effects; nor does it say how these results relate to our hypotheses. In the next step, we therefore focus on the estimated parameters from Model 8. As we need to consider seventy parameters and their combinations to get a full grasp of the patterns describing racial heterogamy, we do not present the parameters themselves. Instead, we report the estimated number of White/non-White couples for 1,000 homogamous couples within the category sorted by the couple's immigration status and the place of residence (see Table 4). We must note that these values represent the estimated number of White/non-White unions *after controlling for* the size of the respective populations.

Model 8 confirms our first hypothesis that different visible minorities in Canada face different odds of forming a union with a White person. If we look at the total number of heterogamous couples (irrespective of their immigration status and metropolitan area), we find that Blacks, Chinese, and Latin Americans display the highest odds of inter-partnering with a White person. If we calculate averages across metropolitan areas and immigration status<sup>11</sup>, we estimate an approximate number of 73 Black/White, 51 Chinese/White, and 47 Latino/White couples for 1,000

---

<sup>11</sup> We can illustrate this process with an example of Black/White couples. The estimated number of Black/White couples is 661 ( $42 + 35 + 124 = 201$  in Montreal,  $83 + 25 + 91 = 199$  in Toronto, and  $127 + 29 + 105 = 261$  in Vancouver). Each of these numbers relates to 1,000 homogamous couples in the given category. Thus, the total of 662 relates to the 9 subgroups (3 in Montreal, 3 in Toronto, and 3 in Vancouver). As  $662/9 = 73.4$ , we estimate 73 Black/White couples per 1,000 homogamous unions on average.

homogamous couples. In contrast, Koreans and West Asians have the lowest odds of crossing a racial boundary and we estimate that only approximately 15 Korean/White and 11 West Asian/White unions are found per 1,000 endogamous couples.

The high level of exogamy noted for Blacks in Canada stands in clear contrast with the findings from the United States. However, as we already mentioned, the U.S. and Canadian Blacks did not share the same historical experience (see section 2). Our finding also corroborates other studies that suggest that the low levels of Black-White unions found in the United States are not universal. For example, Model and Fisher (2002) showed that Blacks living in England are significantly more likely to have a White partner than their U.S. counterparts. Similarly, Muttarak (2004) showed that Black Caribbeans have the highest intermarriage rates among all British non-White groups.

Our second hypothesis suggested that different visible minority groups might face different odds of interracial pairing depending on whether they live in Montreal, Toronto, or Vancouver. Let us first ignore the variation across immigration status and focus on the total number of heterogamous couples in the three cities. Our data suggest that the Blacks' higher tendency to partner with Whites is general and applies to all three metropolitan areas. However, the relative position of other groups varies widely. In Montreal, Blacks are followed by non-Asian groups (Latinos and Arabs) with regards to forming a union with a non-minority partner. Averaging across immigration status, our model predicts 67 Black/White unions, 63 Latino/White unions, and 48 Arab/White unions per 1,000 homogamous couples in

1  
2  
3 Montreal. In Toronto and Vancouver, Blacks are followed by Asian groups. In  
4  
5 Toronto, for instance, our model estimates 66 Black/White, 49 Chinese/White, and  
6  
7 47 South Asian/White (closely followed by 46 Latino/White) unions per 1,000. In  
8  
9 Vancouver, we predict 87 Black/White, 66 Chinese/White, 61 Filipino/White, and  
10  
11 60 Japanese/White couples per 1,000 (averages across immigration statuses).  
12  
13

14  
15  
16  
17 <Table 4 >  
18  
19

20  
21  
22 We also hypothesized that the tendency towards racial heterogamy might  
23  
24 depend on the population size of the given visible minority in each area. We found  
25  
26 that some Asian groups (Chinese, Japanese) are more likely to interpartner in  
27  
28 Vancouver where they represent a larger portion of the population than in Montreal  
29  
30 and Toronto (see Table 4). However, the same principle does not apply to all groups,  
31  
32 in particular to Blacks. In Vancouver, only 0.99 per cent of male residents and 0.87  
33  
34 per cent of females are Blacks (see Table 1). In contrast, approximately 4 per cent of  
35  
36 residents of Montreal and 6 per cent of Toronto's population declared a Black status.  
37  
38 However, Black/White unions are proportionately more frequent in Vancouver than  
39  
40 they are in Toronto.  
41  
42  
43  
44

45  
46 Furthermore, we predicted that Montreal's population was likely to exhibit a  
47  
48 generally weaker predisposition towards interracial heterogamy than the residents of  
49  
50 the other two cities. The easiest way to assess the overall levels of heterogamy in  
51  
52 these cities is to consider region specific odds of crossing a racial barrier derived  
53  
54 from Model 2. The estimated value of the interaction term **INTERMAR\*CITY** in Model  
55  
56  
57  
58  
59  
60

1  
2  
3 2 was 0.441 for Toronto and 0.767 for Vancouver (estimates not reported in a table).  
4  
5 This means that residents of Toronto and Vancouver have respectively 1.55 times  
6  
7 and 2.15 times higher odds of forming a White/non-White union than Montreal's  
8  
9 population [ $\exp(0.441) = 1.55$ ;  $\exp(0.767) = 2.15$ ]. This finding confirms our  
10  
11 prediction about lower levels of White/non-White unions in Montreal. However, as  
12  
13 we will show below, important variations exist across visible minority groups and  
14  
15 immigration statuses (see also Figures 1a and 1b).  
16  
17  
18

19  
20 Let us first examine couples formed by two Canada-born individuals. In  
21  
22 comparison to Montreal, couples living in Toronto have 2.67 times higher odds of  
23  
24 being interracial and those living in Vancouver 3.36 higher odds of being so<sup>12</sup>. After  
25  
26 controlling for the size of the population and averaging across racial groups, we  
27  
28 estimate the average number of White/non-White couples to 13 per 1,000 in  
29  
30 Montreal, 36 in Toronto, and 45 in Vancouver. Figure 1a suggests that this trend  
31  
32 applies to all groups except Arabs who have higher odds of partnering with Whites  
33  
34 in Montreal than in Vancouver<sup>13</sup>.  
35  
36

43  
44  
45

46 <Figure 1a and 1b >  
47  
48  
49  
50

51 The picture is however quite different if we look at unions involving at least  
52  
53 one immigrant (not born in Canada but arrived before age 17). When considering  
54  
55

---

56 <sup>12</sup> These estimates are based on the total sums of the estimated heterogamous couples. For example,  
57 the sum of the 1<sup>st</sup> and 4<sup>th</sup> column in Table 4 is 134 and 358 ( $358/134 = 2.67$ )  
58

59 <sup>13</sup> The figure suggests that the same applies to Koreans and Latinos. However, their odds ratios are  
60 close to 1.

1  
2  
3 unions formed by an immigrant and a non-immigrant ('mixed immigration status'),  
4  
5  
6 Montreal's couples have 1.31 times higher odds of racial inter-partnering than those  
7  
8 living in Toronto (see Figure 1b) and 1.18 times higher odds than their counterparts  
9  
10 from Vancouver. The high levels of racial heterogamy observed among these  
11  
12 couples in Montreal must however be interpreted in the light of the fact that  
13  
14 Montreal's residents have significantly lower odds of entering a union with an  
15  
16 immigrant. In other words, native born Quebecers are less likely to enter a conjugal  
17  
18 union with an immigrant but once they do so, they are more open to cross an  
19  
20 interracial barrier.  
21  
22  
23

24  
25 The conclusion that Montrealers who marry or cohabit with an immigrant are  
26  
27 more likely to enter an interracial union than similar couples in Vancouver and  
28  
29 Toronto also holds for unions of two immigrants. An immigrant marrying or  
30  
31 cohabiting with another immigrant who lives in Montreal has 1.23 times higher odds  
32  
33 of crossing the divide between Whites/non-Whites than his/her counterpart living in  
34  
35 Toronto and 1.16 times higher odds of doing so than one residing in Vancouver. We  
36  
37 suggest that the relatively high inclination of two-immigrant couples towards racial  
38  
39 heterogamy in Montreal is partly a consequence of the low propensity of French  
40  
41 Canadians to marry or cohabit with an immigrant. As immigrants are 'pushed out' of  
42  
43 the native conjugal market, they are 'pushed towards' unions with other immigrants,  
44  
45 including those of different racial origins.

51  
52

It is also instructive to look at visible minority groups separately (see Figure 1b)<sup>14</sup>. When restricting the analysis to unions involving at least one immigrant, 7 out of 10 minority groups are found to be more likely to cross the racial boundaries in Montreal than in Toronto. Similarly, 6 out of 10 groups have higher odds of having a White partner if they live in Montreal than in Vancouver. This effect is the strongest for Arabs and South-East Asians, i.e. among groups that exhibit the highest proportion of French-speaking immigrants (see section 5.4 for the effect of language).

59  
60

The previous paragraphs concentrated on differences across the metropolitan areas and on how these differences are influenced by immigration status. We can consider the same data using a different perspective, and focus more closely on the effect of the immigration status itself (see Figures 2a-2c and Table 4). Our fourth hypothesis predicted that the patterns of racial exogamy might largely differ depending on whether the individual is an immigrant or not. Our analysis confirms this prediction. First, significant differences are found in the total number of ‘White’ – ‘non-White’ couples within each immigration status (see Table 4). Unions made up of an immigrant and a non-immigrant (mixed immigration status) have the highest odds of being interracial, while unions between two immigrants are generally the least likely to be racially heterogamous. To illustrate this result, we

---

<sup>14</sup> This figure concerns both couples with mixed immigration status and unions between two immigrants as Model 8 does not include a three-way interaction between **HETEROG\*** **BOTHIMMIG\***CITY.

1  
2  
3 again calculated the average number of White/non-White couples for each  
4  
5 immigration status.  
6  
7

8 Our model estimates the number of racially heterogamous unions at 61 per  
9  
10 1,000 among couples with mixed immigration status; 31 among couples consisting  
11  
12 of two native born; and 19 among unions between two immigrants (averages across  
13  
14 the visible minority groups and metropolitan areas). However, Figures 2a-2c show  
15  
16 that the population of Montreal significantly departs from this pattern. In this city,  
17  
18 the native born couples are less likely to involve partners of different racial origins  
19  
20 not only when compared to mixed immigrant couples but also in comparison with  
21  
22 unions between two immigrants.  
23  
24  
25  
26  
27  
28  
29

30 <Figures 2a – 2c>  
31  
32  
33

34 Again, it is useful to consider variation across visible minority groups (see  
35  
36 Figures 2a to 2c). In all three cities, the immigration status exerts the strongest  
37  
38 influence on the level of racial heterogamy for West Asians and Latinos.  
39  
40 Furthermore, West Asians in Toronto and Vancouver and Latin Americans in  
41  
42 Vancouver are exceptions to the rule that unions of two native born individuals tend  
43  
44 to be more heterogamous than unions of two immigrants. Among these two visible  
45  
46 minority groups, the lowest level of exogamy is found among those born in Canada  
47  
48 who partnered with another native born Canadian. In contrast, Japanese in Toronto  
49  
50 and Blacks and Chinese in Vancouver have higher odds of entering an interracial  
51  
52 union if both spouses were born in Canada.  
53  
54  
55  
56  
57  
58  
59  
60

#### 4.4. Language factor

French language is an important factor in delimiting cultural boundaries in Quebec, and so we hypothesized that language should be one of the major factors influencing the odds of racial heterogamy in this province. French speaking minorities might be perceived as members of the wider ‘French family’ and the language might weaken the effect of race. The fact that immigrants from groups with the highest proportion of French native speakers (e.g. Arabs or South East Asians) tend to interpartner more easily in Montreal than in Toronto or Vancouver reinforces this hypothesis (see p. 21).

Ideally, we should have tested this hypothesis by adding the language dimension to our log-linear models. Unfortunately, this would require a seven-way table with at least 5,808 cells and our sample is not large enough to accommodate this type of analysis. To solve this problem, we merged all visible minorities into one group, i.e. we distinguish only between ‘Whites’ and ‘non-Whites’. Furthermore, we created a new variable ‘mother tongue’ indicating whether an individual’s mother tongue corresponds to the principal language in the area (i.e. French for respondents from Montreal and English for residents of Toronto and Vancouver). This variable will help us evaluate whether French Canadians are more inclusive of their language counterparts than English speakers are elsewhere in Canada.

We do not offer a detailed description of these models but only briefly present the main findings. We did not find any support for the thesis that French

Canadians might be more inclusive of their linguistic counterparts than Anglophones elsewhere in Canada. The difference between Toronto's and Montreal's populations was not significant, i.e. non-White Francophones in Montreal do not mix more easily than non-White Anglophones in Toronto. Moreover, contrary to our prediction, non-White Anglophones in Vancouver were found to have odds of entering into a union with a White person that are approximately twice as high as their Francophone counterparts in Montreal.

## 6. Conclusions

Canada was the first country in the world to officially adopt a policy of multiculturalism. Its goal was the preservation of various cultures and harmonization of race relationships (Fleras and Elliot, 1992). The relative openness towards interracial conjugal unions might indicate that the policies promoting harmonious inter-racial interactions are successful. While racial intermarriage does not necessarily mean full acceptance of minorities (Song, 2009), it indicates an important weakening of the barriers between the groups and suggests a more hospitable environment for minority individuals.

Driedger (1996) argued that multiculturalism is most deeply rooted in the Canadian West. If multiculturalism encourages harmonious interracial relationships – and consequently also racial intermarriage – we should find the highest propensity to cross racial barriers in Vancouver. Our analysis confirms this expectation as odds of forming an interracial couple are indeed higher in Vancouver than in Toronto or Montreal. Toronto – a city that was historically uniformly Anglophone but has been

1  
2  
3 actively encouraging multicultural policies for several decades – closely follows.  
4  
5  
6 Montreal seems to display the lowest openness towards interracial relationships, but  
7  
8 this finding applies only to unions between two native born Canadians.  
9

10  
11 As we showed, the odds of crossing the White/non-White barrier vary across  
12  
13 visible minority groups. Controlling for the number of men and women in a given  
14  
15 visible minority, we found that Blacks have the highest odds of marrying a White  
16  
17 person in Canada. In Toronto and Vancouver, Blacks are followed by Asian groups.  
18  
19 In Montreal, the second and third positions are occupied by Latinos and Arabs. The  
20  
21 fact that Blacks living in Canada have the highest levels of interracial pairing with  
22  
23 Whites among all the visible minority groups stands in stark contrast with findings  
24  
25 from the United States (Qian and Lichter, 2001, Harris and Ono, 2005, Heaton and  
26  
27 Jacobson, 2000) but corresponds to the situation of Black Caribbeans in the UK  
28  
29 (Song, 2009, Muttarak, 2004). This points out to important differences between  
30  
31 these countries regarding their Black communities. If levels of exogamy reflect the  
32  
33 strength of group boundaries and the degree of minority's integration, our analysis  
34  
35 suggests that the Canadian – as well as the British – Black community is  
36  
37 significantly more integrated compared to that in the United States.  
38  
39  
40  
41  
42

43  
44 Our principal analysis was supplemented by models describing the effect of  
45  
46 mother tongue. If Quebec policy of pre-selecting immigrants who are likely to  
47  
48 integrate into a francophone society is successful, French speaking visible minorities  
49  
50 should intermarry more easily with French speaking Whites. However, our data do  
51  
52 not confirm this hypothesis. On the contrary, we found that native born speakers of  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 the majority language break the racial barrier more easily in Vancouver than in  
4  
5 Montreal.  
6

7  
8 As pointed out at the beginning of the paper, this study did not attempt to  
9  
10 identify all important factors that may affect the choice of one's partner. Rather, we  
11  
12 aimed to document the levels of interracial pairing in Canada as a first step toward  
13  
14 understanding the dynamic of interracial unions in this country. Nevertheless, our  
15  
16 analysis raises interesting questions about the differences between the United States,  
17  
18 Canada, and Great Britain. We believe that our finding regarding the high level of  
19  
20 White/Black intermarriage in Canada is valid but it is possible that the relative  
21  
22 position of other groups may be partly driven by differences in the racial  
23  
24 classification used in each country.  
25  
26  
27

28  
29 For example, the studies from the United States use only four broad pan-  
30  
31 ethnic groups, while the Canadian classification distinguishes ten non-White  
32  
33 categories. In the UK, the term black has traditionally referred to a wide category of  
34  
35 non-Whites (Song, 2004). Even though more attention was paid to account for the  
36  
37 diversity of the non-White population in recent years, the British ethnic groups still  
38  
39 do not directly compare to the Canadian classifications. Moreover, the U.S. statistics  
40  
41 merge all people originating from Europe, the Middle East or North Africa into a  
42  
43 White category. In contrast, the Canadian classification separates those "Caucasian  
44  
45 in race or white in skin colour" from West Asian or Arabs. These classification  
46  
47 differences undoubtedly influence how racial endogamy is defined in each country  
48  
49 and, consequently, the estimated levels of intermarriage. Clearly, more direct  
50
