3 ABSTRACT  
4

5 It is increasingly acknowledged that clusters do not necessarily exhibit  
6 networks of local collective learning. Through a case-study of Sophia-Antipolis  
7 this study investigates to what extent networks of collective learning emerged  
8 throughout the growth of the business park. A longitudinal analysis of the  
9 inventor networks of its two main sectors reveals that a local network of  
10 collective learning emerged only in Information Technology and not in Life  
11 Sciences. Through the creation of spin-offs and high-tech start-up firms the  
12 initial dominance of large multinationals decreased only in Information  
13 Technology. This suggests that small firms play an important role in  
14 establishing local networks.

## 1. INTRODUCTION

The business park of Sophia-Antipolis originates from the private initiative of Pierre Laffitte to turn a 'greenfield' site just off shore the Côte d'Azur into a high-tech park. Partly due to public support and marketing, high-tech activities started to be located there from the 1970s onwards. International high-tech firms, mainly from Information Technology and Life Sciences industries, that wanted to adapt their products to the requirements of the European market were attracted by favourable locational characteristics like the pleasant climate and the presence of an extensive tourist infrastructure. This implies that the 'cluster' was originally nothing more than pure co-location of high-tech firms, completely lacking a local interaction structure. This has changed through the course of time. It is often argued that Sophia-Antipolis' Information Technology sector is more and more characterized by local knowledge-based interaction among its firms and research institutes, whereas such interaction is less apparent and convincing in Life Sciences (LONGHI 1999; QUÉRÉ 2007).

This story is very much in line with important findings in the recent literature on clusters. It is increasingly agreed upon that it cannot be assumed beforehand that all firms in a cluster are involved in local networks of collective learning (GIULIANI 2007). Consequently, the constructs of clusters and networks need to remain conceptually disentangled. As VISSER (2009, p. 168/169) puts it: "*Clusters refer to spatial concentration processes involving a related set of activities in which context firms may but need not cooperate*". Conversely, *networks refer to (...) cooperation in the form of knowledge exchange between firms and other actors that may but need not develop these links at the local or regional level.*"

1  
2  
3  
4 In other words, clusters and networks do not necessarily coincide. An  
5  
6 important follow-up question, then, is under which conditions clusters exhibit  
7  
8 local collective learning networks. This study examines this relationship  
9  
10 between clusters and networks by means of a longitudinal analysis of the  
11  
12 inventor networks in Sophia-Antipolis' two main sectors. As a cluster  
13  
14 emerges, grows and eventually declines, the conditions under which firms and  
15  
16 individual inventors in that particular cluster interact in networks change as  
17  
18 well. This study takes a closer look at the introductory and growth stages of  
19  
20 the co-evolution of clusters and networks (TER WAL and BOSCHMA 2009b). By  
21  
22 means of a longitudinal analysis of the example case of Sophia-Antipolis, this  
23  
24 paper thus aims to demonstrate how local networks of collective learning  
25  
26 evolved while the cluster emerged and grew. It shows that the extent to which  
27  
28 clusters and networks show overlap might be dependent on the nature and  
29  
30 extent of the spatial clustering of firms in space. In so doing the paper aims to  
31  
32 deviate from the mainstream literature of static cluster studies and to respond  
33  
34 to the increasing need for studies that examine under which conditions local  
35  
36 networks of collective learning emerge.  
37  
38  
39  
40  
41  
42

43  
44 In order to accomplish these aims, the paper proceeds as follows. First,  
45  
46 Section 2 describes how Sophia-Antipolis emerged and grew from the 1970s  
47  
48 onwards. This description is based on interviews with key actors at local  
49  
50 authorities and research institutes and on secondary data sources. Then,  
51  
52 Section 3 reconstructs the evolution of co-inventorship networks throughout  
53  
54 these years on the basis of USPTO and EPO patent data. Co-inventorship  
55  
56 networks are considered as a proxy for local networks of collective learning.  
57  
58 Section 3 also discusses the limitations the use of patent data has for the  
59  
60

1  
2  
3 analysis of the evolution of these networks. In Section 4 these networks are  
4 analyzed with social network analysis techniques, testing propositions on how  
5 they evolved in terms of their geographical orientation, connectivity, path  
6 length and clustering coefficient. By looking at these four dimensions this  
7 study claims to demonstrate if and how an integrated network of collective  
8 learning emerged in the two main sectors of Sophia-Antipolis: Information  
9 Technology and Life Sciences. Finally, Section 5 concludes.

## 22 2. THE EVOLUTION OF THE CLUSTER OF SOPHIA-ANTIPOLIS

23  
24 Nowadays it is widely agreed upon that it is very hard to create clusters or  
25 innovation systems in an artificial way through planning or regional policy  
26 (MARTIN and SUNLEY 2003). Cohesive clusters and innovation systems are  
27 mostly considered as being the result of 'natural' developments, which at best  
28 can be facilitated or further stimulated by policy initiatives. Sophia-Antipolis  
29 constitutes a quite unique example of a cluster in that it is to a large extent  
30 created artificially. This section aims to describe the emergence and growth of  
31 Sophia-Antipolis from a qualitative perspective. It is based on interviews with  
32 key actors within the political and academic spheres of Sophia-Antipolis. To  
33 be precise, in October 2006 interviews were conducted at the four key public  
34 and semi-public authorities that are involved in economic development policy  
35 in Sophia-Antipolis<sup>i</sup> and with the representatives of knowledge valorisation of  
36 the four main research institutes in the field of Information Technology and  
37 Life Sciences within Sophia-Antipolis<sup>ii</sup>.

### 59 Emergence

1  
2  
3 Although Sophia-Antipolis is an artificially created cluster, the starting point  
4 was not in the public sphere. The very beginning of Sophia-Antipolis stems  
5 from the private initiative of Pierre Laffitte (Member of the Board of the “Ecole  
6 Nationale Supérieure des Mines de Paris”) in the late 1960s, early 1970s. He  
7 envisioned “a City of Science, Culture and Wisdom” in the South of France  
8 where its participants would be attracted by the so-called Sunbelt effect, i.e.  
9 the pleasant climate and other comfortable living conditions. He acquired a  
10 forested plain between Antibes and Valbonne at the French Côte d’Azur in  
11 order to realise his plans. This area can be viewed upon as a ‘vacant space’  
12 or ‘greenfield site’, lacking any industrial or university tradition (LONGHI 1999).  
13 The first buildings arose in 1972.

26  
27  
28

29 The initial project ended up soon in severe budgetary problems. The  
30 high costs of providing the necessary infrastructure did not outweigh the  
31 benefits that accrued from the initiative. However, being interested to diversify  
32 the economy of the Côte d’Azur from mere tourism, the local public authorities  
33 supported the initiative already in an early stage and soon the project  
34 transformed completely from a private initiative into a public one. With this  
35 transformation the focus of the project shifted more explicitly towards high-  
36 tech activities, since this type of activity could easily complement tourism  
37 without causing negative externalities (e.g. pollution) to the region’s main  
38 economic resource (QUÉRÉ 2002, 2007).  
39

46  
47  
48  
49  
50  
51  
52

53 From the late 1970s, the agglomeration of firms and employment in the  
54 park started (see figure 1). This can be considered the first phase of  
55 development of the business park of Sophia-Antipolis and consisted mainly of  
56 the entry of non-European firms that wanted to open an R&D facility in which  
57  
58  
59  
60

1  
2  
3 they could adapt their products to the specific requirements of the European  
4 market. Although it did not result from an explicit strategy, particularly  
5 Information Technology firms – and to a lesser extent firms in the Life  
6 Sciences and Energy industries – turned out to be attracted to Sophia-  
7 Antipolis (LONGHI and QUÉRÉ 1997).

8  
9  
10  
11  
12  
13  
14  
15 Three main reasons can be held responsible for this successful take-off  
16 (QUÉRÉ 2002). First, there are some structural characteristics of the region  
17 that made the Côte d'Azur, in itself a region without any prior industrial  
18 tradition, an attractive region for foreign investment. These characteristics  
19 included the pleasant climate and other natural conditions, the presence of an  
20 extensive tourist infrastructure, including an international airport, but also  
21 conference rooms, hotels etc. The newly arrived firms could benefit easily  
22 from this physical infrastructure. Second, but not less importantly, the local  
23 authorities developed an explicit and active advertising strategy to promote  
24 Sophia-Antipolis as a high-tech business park, especially in the United States.  
25 A third factor that stimulated the increasing concentration of firms in Sophia-  
26 Antipolis was the explicit decentralisation policy the French government  
27 exerted during the 1970s in order to promote economic development outside  
28 the traditional booming regions (LONGHI 1999). In this light the early arrival of  
29 France Télécom in the area can be seen as a crucial development. France  
30 Télécom provided a modern and efficient fibre-optical network that worked out  
31 as an important pull factor for other Information Technology firms, which could  
32 use this advanced infrastructure base to develop applications readily and  
33 efficiently (LAZARIC et al. 2008).

### FIGURE 1 ABOUT HERE ###

In short, as is often the case in the early emergence of clusters (ARTHUR 1994; MASKELL and MALMBERG 2007), the initial concentration of firms in Sophia-Antipolis has shown to depend considerably on serendipitous factors. First of all, the visionary pioneer Pierre Laffitte happened to be located in the region. Moreover, the attraction of international firms' subsidiaries to Sophia-Antipolis on the basis of its pleasant climate is at least remarkable, especially when considering the completely lacking industrial tradition in the region and the wide set of alternative locations across Europe. The subsequent take-off of the growing concentration of firms, however, has been much less dependent on chance factors. The active promotion strategy and the creation of the first agglomeration advantages – for instance related to France Télécom's internet infrastructure – further stimulated the concentration of firms in Sophia-Antipolis. Or as BRENNER (2004) puts it, local self-augmenting processes were put in place that reinforced the initial forces towards spatial clustering.

#### Intermediate crisis

At the end of the 1980s and beginning of the 1990s the growth process in terms of number of firms and employment started to slow down, particularly in Sophia-Antipolis' main sector of Information Technology. The business park of Sophia-Antipolis started to suffer from a number of important shortcomings. First, it lost competitiveness relative to other regions concerning the attraction of international companies, since those companies changed and expanded

1  
2  
3 their set of location requirements and got a deeper knowledge of the  
4 alternatives. Ireland and Scotland, for instance, could provide cheaper  
5 qualified labour in comparison to Sophia-Antipolis, while central cities like  
6 Paris and London offered a closer proximity to customers and/or financial and  
7 administrative services (QUÉRÉ 2002). Whereas Sophia-Antipolis was highly  
8 competitive in the 'globalisation regime' of the 1980s, the park did not keep  
9 pace with the changing nature of globalisation in the 1990s. In the 1980s  
10 companies were to a large extent vertically integrated and firm location  
11 decisions were mainly based on costs and the presence of facilities. In the  
12 1990s, however, these decisions started to be based more on locational  
13 features that might stimulate innovation (LONGHI 2002; LAZARIC et al. 2008),  
14 since high-tech firms acknowledged more the importance of knowledge from  
15 outside the company for reaching innovation. As a consequence of this shift in  
16 locational preferences, the growth of the number of companies in Sophia-  
17 Antipolis stagnated and some of the established companies even decided to  
18 relocate to other areas (QUÉRÉ 2002).

19  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41 A second, related shortcoming concerns Sophia-Antipolis as a cluster  
42 of innovative activity. Beside the fact that through the course of time many  
43 companies had been attracted on site that did not focus explicitly on R&D,  
44 innovation in Sophia-Antipolis took place exclusively within the boundaries of  
45 the firms. In other words: until the end of the 1980s at least, Sophia-Antipolis  
46 was not a cluster in the 'Porter' sense, where innovations accrued through  
47 interaction of related firms. By contrast, it was nothing more than a  
48 concentration of firms that were co-located on the basis of a similar set of pull  
49 factors. Obviously, the local agglomeration process of related firms is a  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 necessary, but insufficient condition for constituting an innovation system  
4 (LONGHI and QUÉRÉ 1997). Considering also, that most of the companies did  
5  
6 not have their market locally, Sophia-Antipolis could be viewed upon as a  
7  
8 compilation of highly footloose firms (QUÉRÉ 2002). In other words: Sophia-  
9  
10 Antipolis functioned as a 'satellite platform', as defined by MARKUSEN (1996),  
11  
12 where the companies due to their international background had a wide array  
13  
14 of international relations beyond the cluster's boundaries, whereas local  
15  
16 interactions were almost completely absent (LONGHI 1999; LAZARIC et al.  
17  
18 2008).  
19  
20  
21  
22  
23  
24  
25  
26

### 27 Growth

28  
29 After the crisis in the early 1990s the Information Technology and Life  
30  
31 Sciences industry in Sophia-Antipolis show a strongly divergent pattern of  
32  
33 development. In the Information Technology industry it is exactly the 'crisis' of  
34  
35 the disappearing international firms that triggered important endogenous  
36  
37 developments. The relocating international companies left a pool of highly  
38  
39 qualified labour that to a large extent did not move along with the company,  
40  
41 but that wanted to stay in the Côte d'Azur region. Many of those people  
42  
43 started their own firm. Consequently, the shock of the shrinking presence of  
44  
45 multinationals provided a stimulus for stronger locally-based growth of the  
46  
47 park that resulted in the emergence of technologically advanced SMEs  
48  
49 (QUÉRÉ 2007).  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

### FIGURE 2 ABOUT HERE ###

1  
2  
3  
4 This transformation from externally-driven to locally-based growth in the IT  
5  
6 industry was further reinforced by the arrival of public and private education  
7  
8 and research institutes in Sophia-Antipolis. Most of these institutes, like the  
9  
10 University of Nice Sophia-Antipolis, INRIA (National Research Institute on  
11  
12 Informatics and Automation) and CNRS (National Centre of Scientific  
13  
14 Research), were not present on site already in the early stages of  
15  
16 development of the park, but were established from the mid-1980s only. The  
17  
18 same holds for the European authority on Telecommunication Standards  
19  
20 (ETSI), which has been located in Sophia-Antipolis since 1989. Considering  
21  
22 that generally most of the attempts to build a science park start with the  
23  
24 location of research institutes in the park, this makes Sophia-Antipolis an  
25  
26 atypical, 'reverse' science park (QUÉRÉ 2007). The research institutes have  
27  
28 been attracted in the late 1980s on the basis of an explicit strategy of the  
29  
30 national and regional authorities to promote synergies between science and  
31  
32 industry. These synergies consist largely of building a highly qualified local  
33  
34 labour market, but also include PhD students doing traineeships or research  
35  
36 projects in firms.  
37  
38  
39  
40  
41  
42

43  
44 These new developments mainly concerned the Information  
45  
46 Technology industry in Sophia-Antipolis. Three important differences between  
47  
48 the Information Technology and Life Sciences sector can be observed. First,  
49  
50 there is a large difference between the two industries in the total number of  
51  
52 firms that have been concentrated locally. Information Technology  
53  
54 experienced a shift from growth led by foreign multinationals to growth mainly  
55  
56 based on local spin-offs and high-tech start-ups. Hence, for this industry the  
57  
58 crisis turned out to be only a relatively short interruption between the initial  
59  
60

1  
2  
3 emergence of the cluster and the subsequent follow-up phase of extensive  
4 growth (see Figure 2). The period of transition from externally-driven to  
5 locally-based growth took off from the first half of the 1990s onwards and still  
6 continues nowadays. By contrast, the concentration of Life Sciences firms  
7 was not strongly affected by the crisis, but at the same time did not show an  
8 increase in the second half of the 1990s, such as in the Information  
9 Technology sector. As Figure 2 shows, the growth of the number of firms in  
10 the Life Sciences sector has always proceeded at a lower rate than in the  
11 Information Technology sector. The increase of the number of Life Sciences  
12 firms came to a hold in the 1990s. Nowadays, Information Technology firms  
13 constitute about 75% of Sophia-Antipolis' high-tech companies, whereas Life  
14 Sciences firms make roughly 13% (SYMISA 2004). Consequently, from the  
15 middle of the 1990s onwards Sophia-Antipolis specialised progressively  
16 towards Information Technologies at the relative expense of Life Sciences  
17 companies (see Figure 2) and Energy and Earth Sciences.

60

Second, the increasingly locally-based growth in Information Technology made this sector diversify in terms of size. Whereas the park was strongly dominated by large firms in the early stages, the changing nature of growth in the Information Technologies industry resulted in an increasing share of small- and medium sized enterprises. The Life Sciences sector, however, is nowadays still largely dominated by relatively large subsidiaries of international pharmaceutical companies such as Dow Chemical, Allergan and Sanofi-Aventis.

Third, the cognitive distance seems smaller between firms in Information Technology than in Life Science. Partly due to the presence of the

1  
2  
3 European Telecom Standardization Institute (ETSI), most of the Information  
4  
5 Technology firms work in segments of the same value chain (Krafft 2004).  
6  
7  
8 Nowadays, Sophia-Antipolis' IT sector consists of three main building blocks:  
9  
10 infrastructure (equipments, networks and hardware), platforms (interfaces and  
11  
12 software) and applications (including services). These three building blocks  
13  
14 are more or less equally present in Sophia-Antipolis and are strongly related  
15  
16 to each other (Krafft 2004). The interrelatedness of the products and services  
17  
18 they develop positively affects the opportunities for collaboration and  
19  
20 collective learning. This potential is increasingly perceived also by public and  
21  
22 private stakeholders in IT in Sophia-Antipolis. An important private initiative in  
23  
24 this respect is made by the Telecom Valley Association, which aims to map  
25  
26 competences of agents in the park and promotes the emergence of clubs and  
27  
28 associations in an attempt to link small firms, large firms and research  
29  
30 institutes in the field of Information Technology (LONGHI 1999; LAZARIC et al.  
31  
32 2008). In the Life Science sector, however, the cognitive distance between  
33  
34 agents seems much larger. The activities within the sector range from drugs,  
35  
36 biotechnology and cosmetics to medical equipment and fine chemistry.  
37  
38 Hence, the specializations among Life Sciences companies in the park differ  
39  
40 largely and, hence, the potential for complementarities might be rather limited  
41  
42 (LONGHI 1999).  
43

### 53 3. THE CO-EVOLUTUION OF CLUSTERS AND NETWORKS

54  
55 The foregoing section demonstrated that the Information Technology and Life  
56  
57 Sciences industries within the cluster of Sophia-Antipolis show a divergent  
58  
59 evolution path in terms of the emergence and growth of the cluster. Not only  
60

1  
2  
3 has the total growth of the number of firms in Information Technology been  
4  
5 bigger, from the first half of the 1990s the growth has also been based  
6  
7 increasingly on local spin-offs and high-tech start-ups, whereas the growth of  
8  
9 Life Science remained dependent mainly on the growth of multinational  
10  
11 enterprises. This paper argues that these differences in the evolution path of  
12  
13 spatial clustering have implications for how local networks of collective  
14  
15 learning evolve. When a cluster emerges and grows, the size and composition  
16  
17 of its set of firms is subject to change. This has direct implications for the  
18  
19 potential for local collective learning and can be considered the basic  
20  
21 mechanism that couples cluster dynamics and network dynamics into a  
22  
23 process of co-evolution. More specifically, two main mechanisms link the  
24  
25 emergence and growth of a cluster to the evolution of its network of local  
26  
27 collective learning. More specifically, two main mechanisms link the  
28  
29 emergence and growth of a cluster to the evolution of its network of local  
30  
31 collective learning.  
32

33  
34 First, the higher the local concentration of inventors active in a certain  
35  
36 technology, the more opportunities for local collective learning emerge. A local  
37  
38 concentration of firms doing similar things will facilitate knowing about each  
39  
40 others' activities – and hence the potential for collective learning – at low cost  
41  
42 (MALMBERG and MASKELL 2002). Since the total concentration of firms and  
43  
44 research institutes is much larger for Information Technology than for Life  
45  
46 Sciences, it is expected that a critical mass of agents for collective learning  
47  
48 will only have been reached in Information Technology and not in Life  
49  
50 Sciences (LONGHI and QUÉRÉ 1997; QUÉRÉ 2007).  
51  
52  
53

54  
55 Second, the formation of high-tech start-ups and the emergence of  
56  
57 spin-off companies in the Information Technology sector might contribute to  
58  
59 the emergence of a local collective learning milieu. Spin-offs and high-tech  
60

1  
2  
3 start-ups tend to maintain linkages with the incumbent firm, research institute  
4 or university. Spin-offs inherit capabilities from the incumbent organization  
5  
6 (KLEPPER and SLEEPER 2005) and – due to myopia (LEVINTHAL and MARCH  
7  
8 1993; MASKELL and MALMBERG 2007) – tend to do relatively similar things as  
9  
10 the incumbent firm. As a consequence, these firms have a strong potential for  
11  
12 collective learning with the incumbent firm and its partners right from the start.  
13  
14 Furthermore, both high-tech start-ups and spin-off firms signal the presence of  
15  
16 a highly qualified and relatively mobile labour market. Mobility of highly  
17  
18 qualified personal across firms is an important channel of unintended, though  
19  
20 valuable forms of collective learning (ALMEIDA and KOGUT 1999). The research  
21  
22 institutes in Information Technology present on site play a key role in the  
23  
24 creation and maintenance of this labour market.  
25  
26  
27  
28  
29  
30  
31

32 Hence, based on the differences in the clustering process of  
33  
34 Information Technology and Life Sciences industries differences are expected  
35  
36 in whether and to what extent collective learning practices have emerged in  
37  
38 the two main sectors of Sophia-Antipolis. For the Information Technology  
39  
40 industry one expects to observe a trend towards the emergence of a local  
41  
42 collective learning milieu throughout the evolution of Sophia-Antipolis, though  
43  
44 particularly when the growth regime switched from being mainly externally-  
45  
46 driven to mainly locally-based in the middle of the 1990s. For the Life  
47  
48 Sciences industry any such trend towards the emergence of a local collective  
49  
50 learning milieu is not expected to be observable.  
51  
52  
53  
54  
55  
56  
57

#### 58 Detecting local collective learning

59  
60

1  
2  
3 The evolution of the network of collective learning in Sophia-Antipolis is  
4 assessed through an investigation of co-inventorship networks. These  
5 networks capture two important dimensions of a local network of collective  
6 learning. First, a co-inventorship network is a representation of the local  
7 structure of intended knowledge exchange between individual actors (EJERMO  
8 and KARLSSON 2006). The fact that multiple inventors are mentioned on a  
9 single patent document is a clear sign of knowledge-intensive team work,  
10 irrespective of the fact whether or not the inventors mentioned on the patent  
11 worked for the same firm or research institute at the time of innovation.  
12  
13 Second, a co-inventorship network has a strong social connotation. People  
14 who have worked together on the same innovation project (BRESCHI and  
15 LISSONI 2003) or who have worked for the same firm at the same time  
16 (CASPER 2007) have a social relationship that tends to endure over time, even  
17 when they move to another firm or even to another region (AGRAWAL et al.  
18 2006). These types of interpersonal networks are considered an important  
19 channel for the diffusion of technological knowledge (ZANDER and KOGUT  
20 1995; DAHL and PEDERSEN 2004). BRESCHI and LISSONI (2003) and SINGH  
21 (2005) demonstrated that the fact that knowledge spillovers tend to be  
22 localized, is mainly due to the localized nature of social networks. The  
23 underlying network of co-inventorship relations – interpreted as a social  
24 network among engineers – could very well explain the localized pattern of  
25 patent citations. The presence of a cohesive network of this kind in a cluster –  
26 with indirect relationships between inventors in a network – is of utmost  
27 importance for knowledge to circulate locally (NOOTEBOOM and KLEIN-

1  
2  
3 WOOLTHUIS 2005) and can be considered a clear signal for the existence of a  
4  
5 local collective learning milieu.  
6  
7

8 This study considers four different properties of co-inventorship  
9  
10 networks to assess the presence of local collective learning. Among these  
11  
12 density is deliberately disregarded, since density is highly sensitive to network  
13  
14 size and cannot be compared across networks of unequal size. Almost as a  
15  
16 rule density declines with network growth, since the increase of the number of  
17  
18 possible links is quadratic when the number of nodes increases linearly  
19  
20 (FRIEDKIN 1981). Also path length and clustering coefficient are sensitive to  
21  
22 size. In contrast to density, however, these properties can be analysed  
23  
24 longitudinally by comparing the actual values to the values one would expect  
25  
26 in random networks of equal size and density.  
27  
28  
29  
30

31  
32 The first property that is considered in this study is the geographical  
33  
34 orientation of the network of inventors. Since all inventors with whom local  
35  
36 inventors have co-invented are included, the network also encompasses all  
37  
38 linkages from local inventors to non-local (national or international) inventors.  
39  
40 Bearing in mind the original international character of the business park a  
41  
42 strong international orientation can be expected in the emergence and early  
43  
44 growth stages for both sectors. Due to the change from externally-driven to  
45  
46 locally-based growth in Sophia-Antipolis' Information Technology sector one  
47  
48 can expect to observe an increase in interaction between local inventors for  
49  
50 this sector only. The propositions are formulated as follows:  
51  
52  
53  
54  
55  
56  
57

58 ***Proposition 1a:*** *In Information Technology the inventor network has*  
59  
60 *become more locally oriented throughout the growth of Sophia-Antipolis.*

1  
2  
3 ***Proposition 1b:*** *In Life Sciences the inventor network has not become*  
4 *more locally oriented throughout the growth of Sophia-Antipolis.*  
5  
6  
7  
8  
9

10 Here the focus is primarily on the emergence of local collective learning,  
11 although it is acknowledged that it is extremely important for a cluster to be  
12 linked to the outside world as well. The importance of local interaction within a  
13 cluster should clearly not be overstated (WATERS and LAWTON-SMITH 2008).  
14  
15 An 'external gaze' to world that ensures the inflow of codified knowledge  
16 about scientific discovery and technological advancement in the wider  
17 industry is of utmost importance for a cluster and its firms to remain  
18 competitive (AMIN and COHENDET 1999; ASHEIM and ISAKSEN 2002).  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28

29 A second network property that signals local collective learning is the  
30 cohesive nature of the inventor network. The connectivity of a network is  
31 expressed as the proportion of node pairs in a network that can reach one  
32 another by virtue of the existence of a network path. Hence, a network with  
33 high connectivity allows knowledge not only to flow through direct linkages,  
34 but also through indirect linkages (NOOTEBOOM and KLEIN-WOOLTHUIS 2005).  
35  
36 FLEMING and FRENKEN (2007) demonstrated for inventor networks in Silicon  
37 Valley and Boston that through the course of time multiple unconnected sub-  
38 structures in these local networks joined together to form a giant,  
39 interconnected component. In Sophia-Antipolis it is expected that the locally-  
40 based growth in the growth stage of the Information Technology industry has  
41 stimulated the emergence of a network with high connectivity in this sector,  
42 whereas – by contrast – such trend is not expected in Life Sciences. When  
43 looking to the evolution of connectivity in a network, it needs to be  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 acknowledged that fast growing networks will find relative difficulty to retain  
4 high levels of connectivity in comparison to constantly or slowly growing  
5 networks; due to the fact that the number of potential linkages grows in  
6 quadratic terms in a linearly growing network. Since Information Technology  
7 in Sophia-Antipolis is characterized by a much higher number of entrants than  
8 the Life Science sector, the tendency towards more connectivity might be  
9 partly counteracted by the growth of the network in terms of number of  
10 inventors. CASPER (2007), however, found in his study of the inventor network  
11 in the San Diego biotech cluster that connectivity remained high,  
12 notwithstanding the massive growth of the network. Therefore, the  
13 expectations concerning connectivity are formulated as follows:  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30  
31

32 ***Proposition 2a:*** *In Information Technology connectivity of the inventor*  
33 *network has increased throughout the growth of Sophia-Antipolis.*  
34

35 ***Proposition 2b:*** *In Life Sciences connectivity of the inventor network has*  
36 *not increased throughout the growth of Sophia-Antipolis.*  
37  
38  
39  
40  
41  
42

43 The third and fourth properties of a local collective learning network relate to  
44 the presence of a small world structure (WATTS and STROGATZ 1998). A small  
45 world structure combines two network properties that tend to be beneficial for  
46 learning: structural holes and social capital (VERSPAGEN and DUYSTERS 2004;  
47 COWAN et al. 2006). Structural holes refer to the absence of a link between  
48 two partners of a node. If present, that link would produce a closed triangle in  
49 which three nodes are all directly connected to one another. In a network rich  
50 in structural holes certain nodes form the bridge between otherwise  
51

unconnected or weakly connected parts of a network (BURT 2004). These bridges ensure the inflow of novel information into denser parts of the network. As a result, structural holes are held to be important for avoiding situations of cognitive lock-in (GLÜCKLER 2007). The presence of structural holes leads to a short average path length between actors in a network, as a consequence of which knowledge can flow easily throughout the network as a whole. On the other hand, the dense local structures with many redundant ties that also characterize small worlds are generally interpreted as a sign of social capital (COLEMAN 1988; WALKER et al. 1997). The presence of dense local structures – apparent in a high average clustering coefficient – facilitates trust-based and frequent exchange of high-quality information among the actors involved. A small world network that combines a high clustering coefficient with a short path length, then, combines the advantages of efficiency and embeddedness. Accordingly, FLEMING *et al.* (2007) demonstrated that a regional small world structure positively affects regional innovativeness. In this study both a short path length and a high clustering coefficient are viewed as important characteristics of a local collective learning milieu. Thus, one expects to observe a trend towards shorter path lengths and increasing clustering coefficients only in Information Technology, and not in Life Sciences:

***Proposition 3a:*** *In Information Technology a trend towards decreasing average path length of the inventor network can be observed throughout the growth of Sophia-Antipolis.*

#### 29 4. METHODOLOGY

30  
31 Patent documents have come to be a rich source of information on knowledge  
32 production and innovation activity. Although it can be easily argued that  
33 patents do not capture the whole spectrum of innovation activity and,  
34 therefore, patent documents are not the ideal source of information in that  
35 respect, the highly detailed information they contain provides ample  
36 opportunities for studying the geography of innovation activity. For instance,  
37 patents – which are not equally distributed in space – are widely used in  
38 economics as a measure of regional knowledge production (Acs et al. 2002).  
39 Moreover information on patent citations is used for tracing knowledge  
40 spillovers across firms and to investigate the role of geographical or other  
41 forms of proximity in their spatial pattern.  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56

57 A relatively new use of patent data is their application to the  
58 reconstruction of cooperation networks back in time (see for instance BRESCHI  
59  
60

1  
2  
3 and LISSONI 2003; CANTNER and GRAF 2006). In the same vein, this paper will  
4 use patent data to reconstruct the networks of collective learning in which  
5  
6 inventors from Sophia-Antipolis have been involved.  
7  
8  
9

### 10 11 12 Data

13  
14  
15 Two different sources of patent data are used to reconstruct the evolution  
16 of co-inventorship networks: patents from the European Patent Office (EPO),  
17 available for the period from 1978 till 2002, and American (USPTO) patent  
18 data from 1975 till 1999 (HALL et al. 2001). The use of multiple data sources  
19 allows for a reliable analysis of trends in the evolution of the networks, since  
20 the network properties that signal local collective learning can be compared  
21 across the two types of networks. In both cases the patents have been dated  
22 on the basis of the application date – as opposed to the granting date – since  
23 this date is closest to the time the invention was created.  
24  
25  
26  
27  
28  
29  
30  
31  
32  
33  
34  
35

36 Both for EPO and USPTO data the patents were selected on the basis  
37 of the inventor address. Taking the inventor address as the selection criterion  
38 is an appropriate and commonly applied method for allocating patents to the  
39 geographical origin in which the innovation has been factually developed, as  
40 long as the spatial unit of analysis is not too small (i.e. not smaller than a  
41 labour-market area). The underlying reason is that patents developed by a  
42 subsidiary of a multi-establishment firm generally tend to be assigned to the  
43 headquarters, which are possibly located in a different region. The province of  
44 Alpes-Maritimes that surrounds Sophia-Antipolis has been taken as its labour  
45 market area. Thus, for the purpose of this study all patents with at least one  
46 inventor resident in the study area were retrieved from the larger EPO and  
47  
48  
49

55  
56  
57  
58  
59  
60

1  
2  
3 USPTO datasets. Beside all local inventors these subsets of patent data also  
4  
5 contain information about all non-local inventors they are connected to. In that  
6  
7 way, it is possible to compare the extent to which the cooperation takes place  
8  
9 within the local system with the extent to which the system and its actors are  
10  
11 opened up to 'the external world' by means of connections to inventors  
12  
13 outside the local system.  
14

18  
19  
20 ### TABLE 1 AND FIGURE 3 ABOUT HERE ###  
21  
22  
23

24  
25 Table 1 shows the number of EPO and USPTO patents on which the  
26  
27 reconstruction of the networks is based. Patents have been allocated to the  
28  
29 Information Technology, Life Sciences or Miscellaneous categories on the  
30  
31 basis of the main technology class mentioned on the patent document. For  
32  
33 the EPO patents the OST-INPI/FhG-ISI technology nomenclature as  
34  
35 developed by SCHMOCH *et al.* (2003) was used to recode the patent IPC  
36  
37 technology classes into sector codes. Which sectors have been allocated to  
38  
39 the IT and Life Sciences industries is explained in Appendix 1. For the  
40  
41 USPTO patents use was made of the classification as proposed by Hall *et al.*  
42  
43 (2001); the two-digit subcategories that constitute the Information Technology  
44  
45 and Life Sciences industries are specified in Appendix 2. Both for EPO and  
46  
47  
48  
49  
50  
51  
52  
53  
54 Information Technology has been defined in broad terms,  
including also related fields in Electronics, such as semiconductors.

55  
56 As Figure 3 and Table 1 show the patent portfolio of Alpes-Maritimes  
57  
58 has always been dominated by the Information Technology and Life Sciences  
59  
60 sectors, both for EPO and USPTO patents. Since these two sectors are

1  
2  
3 mainly concentrated in Sophia-Antipolis, the dominance of these sectors in  
4 the total number of patents from Alpes-Maritimes justifies the choice of this  
5 surrounding province as the spatial scale of analysis. However, as Table 1  
6 shows, the total number of patents on which the analyses – covering a period  
7 of approximately 20 years – are based is rather limited. Hence, it needs to be  
8 acknowledged that the networks that are constructed on the basis of patent  
9 data are not a full representation of local collective learning practices.  
10 Cooperation activity that did not lead to a patent is not captured by the  
11 methodology. This implies, for instance, that more informal collaborations as  
12 well as unsuccessful collaborations are absent in patent data. More  
13 importantly, Information Technology firms differ in their tendency to protect  
14 their innovations by patents. Especially software producers have a relatively  
15 low tendency to patent (BESSEN and HUNT 2007) and, consequently, will be  
16 underrepresented in patent data. Also smaller firms and research institutes  
17 tend to be underrepresented in patents. These limitations need to be borne in  
18 mind when interpreting the network analysis results.

33  
34  
35  
36  
37  
38  
39  
40  
41 Figure 3 also shows the number of patents and inventors in 5-year  
42 moving windows for each of the data sources. In line with the general trend  
43 towards more patenting, these figures show a nearly constant increase in the  
44 number of patents. Strikingly, the crisis in the first half of the 1990s in IT, as  
45 reported in Section 2, is visible in a decreasing growth rate of the number of  
46 patents. After this crisis, in the second half of the 1990s, one can observe a  
47 strong increase in this growth rate. The increased share of IT-patents in total  
48 number of regional patents confirms this observation.

### Network reconstruction

Co-inventorship networks are used to analyse the emergence of local collective learning in Sophia-Antipolis. In these networks individual inventors are linked when they have worked together on a patent. Making use of information at two distinct levels, a co-inventorship network is a one-mode projection of a two-mode (or bipartite) network between patents and inventors. This study deliberately takes the inventor – and not the firm – as its level of analysis. A firm-level network analysis based on patent data is often problematic, since patents tend to be assigned exclusively to large companies, even when smaller firms or research institutes have (also) been involved. As a consequence, when tracing inter-organizational links in this way many collaboration linkages will not be revealed (TER WAL and BOSCHMA 2009a). However, a network analysis at the individual inventor level as employed in this study largely compensates for this shortcoming; the individual inventors of small firms or research institutes will be mentioned on the patent document, also in case the patent is in possession of a private firm, which has either bought the patent or was involved as a cooperation partner. In fact, it is the mobility of inventors across companies and the involvement of inventors from SMEs and research institutes that potentially link together groups of inventors that work for different local firms. Consequently, this paper builds on the premise that a cohesive and integrated local co-inventorship network signals the presence of a local learning that exceeds firms' boundaries.

For that purpose inventor-level networks are generated in two different ways. The two methods differ from each other in the assumptions they make

1  
2  
3 about how long links between inventors persist. This kind of assumption  
4 needs to be made, since no information on the dissolution of links can be  
5 extracted from patent data. In the first procedure, networks were built using a  
6 5-year moving window procedure. This implies that a network of a particular  
7 year contains all co-inventorship linkages of that year and the preceding four  
8 years. The networks that have been generated this way are used to plot  
9 trends in terms of the geographical orientation and the fragmentation of the  
10 network. The second procedure concerns a cumulative network over the  
11 complete period of investigation. The assumption here is that social links  
12 between inventors persist over time (AGRAWAL et al. 2006), although it needs  
13 to be acknowledged that people might exit the region or the industry. Whereas  
14 the networks generated by the five-year moving window procedure could be  
15 considered more as an approximation of structure of the existent interpersonal  
16 knowledge flows and acts of cooperation in a region (EJERMO and KARLSSON  
17 2006), the cumulative inventor network is more an indication of the ever  
18 growing underlying social network that potentially functions as a network  
19 through which relevant innovation-related knowledge can flow (BRESCHI and  
20 LISSONI 2003). Hence, the networks generated with the five-year moving  
21 window procedure will be used for the analysis of the cooperative structure of  
22 collective learning, whereas analysis of small world properties will be based  
23 on the cumulative inventor network.

#### Measures of local collective learning

55  
56  
57 As explained before, the evolution of the inventor networks in Sophia-Antipolis  
58 and the emergence of collective learning practices are assessed on the basis  
59  
60

1  
2  
3 of four different network properties. A series of propositions formulates the  
4 expectations of how these properties evolve over time for both sectors.  
5  
6

7  
8 The first network property is the geographical orientation of inventors in  
9 the network. Both the EPO and USPTO networks encompass all local actors  
10 and all non-local actors with whom they are linked. Therefore a distinction is  
11 made between network relationships at three spatial scales: local-local, local-  
12 national and local-international interaction.  
13  
14  
15  
16  
17  
18

19  
20 The second property is network connectivity or, inversely, network  
21 fragmentation. As GIULIANI (2007) showed it should not be assumed  
22 beforehand that knowledge networks in clusters are pervasive. Network  
23 fragmentation can be measured in various ways. First, the fragmentation  
24 index is defined as the proportion of nodes in the network that cannot reach  
25 other. This is the case when two nodes belong to different, unconnected  
26 components of the network. The second measure of connectivity is the share  
27 of the network's main component or largest components in terms of number of  
28 nodes or number of links (see also CANTNER and GRAF 2006; CASPER 2007;  
29 FLEMING and FRENKEN 2007). A component in a network is any subset of  
30 nodes between which a direct or indirect network path exists. The largest  
31 component of connected nodes in a network is referred to as the Main  
32 Component. The fragmentation index and the share of the main component  
33 will be computed on the networks generated with 5-year moving window  
34 procedure. As argued before, these are the best approximation of the  
35 evolution of actual collective learning practices in Sophia-Antipolis.  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54  
55  
56

57  
58 The third property is the average path length, computed on the Main  
59 Component of the cumulative inventor network. An average path length that is  
60

1  
2  
3 similar to the value one could expect in a random network of equal size and  
4 density signals small world properties (WATTS and STROGATZ 1998). Therefore  
5 the Path Length ratio is calculated in order to indicate the extent to which the  
6 observed path length differs from the value expected in a comparable random  
7 network. The more the PL-ratio exceeds 1.0, the stronger the small world  
8 nature of the network (UZZI and SPIRO 2005). Since an inventor network as  
9 studied here is a one-mode projection (at the inventor level) of a two-mode  
10 network (of patents and inventors), the Path Length Ratio is calculated as  
11 follows (NEWMAN et al. 2001)<sup>iii</sup>:  
12  
13  
14  
15  
16  
17  
18  
19  
20  
21  
22  
23  
24

$$25 \quad PL_{actual} = \frac{1}{n \cdot (n-1)} \cdot \sum_{i,j} d(v_i, v_j)$$

$$26 \quad PL_{random} = \frac{\ln(n)}{\ln(\mu \cdot \nu)}$$

$$27 \quad PL_{ratio} = \frac{PL_{actual}}{PL_{random}}$$

28  
29  
30  
31  
32  
33  
34

55  
56  
57  
58  
59  
60

A high clustering coefficient is the fourth property of the network of collective learning that is considered. The clustering coefficient is defined as the extent to which the partners of a node are connected among them. At the aggregate level of a network, the clustering coefficient takes the average clustering coefficient across all nodes. An alternative way of calculating the actual clustering coefficient of a network is taking the number of closed triangles (completely connected triads) over the number of 'potential' triangles (a set of three nodes connected by at least two links). The CC ratio compares the

1  
2  
3 actual clustering coefficient to the clustering coefficient that can be expected  
4  
5 in a random network of the same size and density. The further this ratio

actual clustering coefficient to the clustering coefficient that can be expected in a random network of the same size and density. The further this ratio departs from 1.0, the more the network is of a small world nature (Uzzi and Spiro 2005). The formulas for calculating the CC ratio are as follows (NEWMAN et al. 2001)<sup>iv</sup>:

$$CC_{actual} = \frac{3 \cdot \text{number of triangles on the graph}}{\text{number of connected triplets of nodes}} = \frac{\text{number of triangles with at least 3 legs}}{\text{number of triangles with at least 2 legs}}$$

$$CC_{random} = \frac{Mv^3}{Nv^2(\mu^2 + \mu)} = \frac{1}{\mu + 1}$$

$$CC_{ratio} = \frac{CC_{actual}}{CC_{random}}$$

$M$  = number of patents

$N$  = number of inventors

$\mu$  = average number of inventors per patent

$v$  = average number of patents per inventor

## 5. RESULTS

In Section 3 propositions were formulated related to four network properties that detect the emergence of local collective learning: geographical orientation, connectivity, average path length and clustering coefficient. It was argued that only in Information Technology a trend towards local collective learning is likely to be observed during the growth of the park. Not only has growth in IT – in comparison to Life Sciences – been larger in numerical terms, it also has changed in nature; whereas growth initially was dependent on multinational firms in both sectors, growth of the IT sector became increasingly based on local spin-offs and start-ups in the 1990s. The argument was made that the changing nature of the growth process in IT

1  
2  
3 might have induced the emergence of a local collective learning milieu for this  
4 sector of the business park. Consequently, a trend towards more local-local  
5 interaction, stronger connectivity, shorter path lengths and higher clustering  
6 coefficient is expected to be observed for the inventor network in Sophia-  
7 Antipolis' Information Technology sector, whereas such trends towards the  
8 emergence of local collective learning milieu are expected not to be observed  
9 in Life Sciences.

### 19 20 21 22 Geographical orientation 23

24 Figure 4 shows that marked differences can be observed in the geographical  
25 orientation of the Information Technology and Life Sciences inventor networks  
26 (see figure 4). In the IT industry the total number of links is increasing rapidly  
27 over time. However, the number of local linkages only increases in absolute  
28 terms; over the observation period the share of local-local linkages in all co-  
29 inventorship linkages declines from roughly 80 percent to 60 percent. Sophia-  
30 Antipolis' Information Technologies industry is characterized by a strong  
31 connection to the outside world, with the extent of local-international  
32 interaction strongly increasing from the middle of the 1990s onwards. Hence,  
33 there is no support for proposition 1a: the growth of local-local interaction is  
34 clearly counteracted by increased interaction with international partners, as a  
35 consequence of which the relative share of local interaction has not increased  
36 over time.  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53

54 The Life Sciences industry shows a different picture. Most striking is  
55 the relative limited total number of links and its moderate growth rate over  
56 time. Even when bearing in mind the lower total number of patents in Life  
57  
58  
59  
60

1  
2  
3 Sciences, the total extent of inventor interaction is remarkably lower than in  
4 Information Technology (figure 5). The share of local-local interaction is also  
5  
6 consistently lower in Life Sciences than in IT over the entire observation  
7  
8 period and for both data sources. Also in Life Sciences, however, a trend  
9  
10 towards more international interaction can be observed from the middle of the  
11  
12 1990s onwards. However, no clear trend concerning local-local interaction  
13  
14 can be depicted for Life Sciences: in the EPO-based network the relative  
15  
16 share of local-local interaction is clearly decreasing over time, whereas the  
17  
18 USPTO network shows a slightly increasing share of local-local interaction.  
19  
20 Given that no consistent trends (other than increasing local-international  
21  
22 interaction in the 1990s) can be observed, there is support for proposition 1b  
23  
24 that expressed the absence of a trend towards more local-local interaction.

36  
37 ### FIGURES 4 AND 5 ABOUT HERE ###  
38  
39  
40

#### 41 Connectivity

42  
43 Connectivity has been plotted in two ways. First, the fragmentation index  
44  
45 measures the proportion of nodes that cannot reach each other. The second  
46  
47 measure is the share of the Main Component – the largest set of  
48  
49 interconnected nodes – and the Top-5 components in the total number of  
50  
51 nodes in the network.  
52  
53  
54  
55  
56  
57

58  
59 ### FIGURE 6 ABOUT HERE ###  
60

1  
2  
3 The fragmentation index is high for both industries. For Information  
4  
5 Technology an increase in connectivity – i.e. a declining fragmentation index  
6  
7 and an increasing share of the Main Component – is observed at the turn of  
8  
9 the 1980s and 1990s (figure 6). A closer look to the patents of this period  
10  
11 reveals that the dominance of large firms (like Texas Instruments and IBM) in  
12  
13 the total numbers of patent was relatively high in these years. This results in  
14  
15 relatively large groups of interconnected inventors for both of these  
16  
17 companies, causing a decline in fragmentation. Through the course of the  
18  
19 1990s one can observe a strong decrease in connectivity in IT. This decrease  
20  
21 is related to the growth of the network in terms of inventors (and the  
22  
23 exponential growth of the number of dyads), which makes it more difficult to  
24  
25 retain high levels of connectivity. However, unlike the network of the San  
26  
27 Diego Biotech cluster studied by CASPER (2007), the connectivity of the IT  
28  
29 inventor network in Sophia-Antipolis cannot keep pace with its strong growth  
30  
31 in these years. Hence, proposition 2a is not supported. The inventor network  
32  
33 in Life Science shows very constant levels of connectivity through time, both  
34  
35 in the EPO- and USPTO-based networks. Although the inventor network in  
36  
37 Life Science grows slightly over time, and hence it is difficult to prevent a  
38  
39 decline in connectivity, a trend towards increasing connectivity definitely  
40  
41 cannot be observed. Hence, there is support for proposition 2b.  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52

### 53 Path Length

54  
55 Proposition 3a and 3b formulated the expectation that a trend towards shorter  
56  
57 average path length (as compared to the value of a random network of equal  
58  
59 size) to be observed in Information Technology, and not in Life Sciences.  
60

1  
2  
3 Figure 7A shows the Path Length Ratio, calculated on the main components  
4 of the EPO inventor networks, for both industries. The Ratios are reported as  
5  
6 soon as the Main Component's size exceeds 30.  
7  
8  
9

10  
11  
12 ### FIGURE 7 ABOUT HERE ###  
13  
14

15  
16  
17 The more the PL-ratio approximates 1.0, the more the path length is  
18 comparable to the path length in a random network and, hence, the easier  
19 knowledge flows through the network. In Information Technology there is a  
20 clear trend towards shorter path lengths. This is an important signal for the  
21 emergence of a local collective learning milieu: average path lengths get  
22 shorter when links are built that form a shortcut between dense substructures  
23 in a network. These links allow information to flow more easily from one side  
24 of the network to the other. Hence, the core of inventors in Information  
25 Technology gets a more coherent and efficient structure of interaction over  
26 time. In Life Science the opposite trend can be observed: the PL-ratio moves  
27 away from 1.0 over time. This happens when new links added to the network  
28 do not form shortcuts between distant parts of a network, but are instead  
29 reinforces the prior existing, dense substructures of a network. Hence, in Life  
30 Sciences no trend towards a coherent and efficient structure of core inventors  
31 can be observed. Thus there is strong support for propositions 3a and 3b.  
32

52  
53  
54

#### 55 Clustering coefficient

56  
57 Proposition 4a and 4b formulated the expectation that the CC-ratio would  
58 decline over time in IT, whereas such trend would not be observed in Life  
59  
60

1  
2  
3 Sciences. Figure 7B shows that a trend towards decreasing clustering  
4 coefficients cannot be observed in neither of the two sectors. For both  
5 industries the observed clustering coefficients are much lower than could  
6 have been expected in random bipartite networks of the same size. This  
7 implies that *within-team clustering* is high; due to the two-mode nature of the  
8 network all inventors mentioned on a single patent form a clique in the  
9 network. By contrast, *between-team clustering* is lower than could have been  
10 expected at random (Uzzi et al. 2007). Hence, there is no trend towards a  
11 small world structure in terms of clustering coefficients. Therefore, there is no  
12 support for proposition 4a and full support for proposition 4b.  
13

24  
25  
26

27 In synthesis, the longitudinal analysis of inventor networks revealed  
28 marked differences between Information Technology and Life Sciences in  
29 Sophia-Antipolis. A local collective learning milieu has evidently always been  
30 non-existent in Life Science; none of the network properties investigated  
31 signalled a trend towards the creation of a local collective learning milieu. For  
32 the case of Information Technology the results are less straight forward; some  
33 network properties point toward a slight trend of an emerging local collective  
34 learning milieu. Even though the inventor network in IT remains fairly  
35 fragmented, the decrease in path length signals the creation of shortcuts that  
36 interlink sub-groups of inventors across the business park. It is particularly  
37 these shortcut links that form an essential element of an integrated and  
38 cohesive network of local collective learning, connecting inventors from  
39 various organizations and sub-disciplines. The differences across Information  
40 Technology and Life Sciences suggest that small local start-up companies  
41 and spin-offs play a crucial role in establishing this kind of links.

## 6. CONCLUSION

Starting from the observation in the literature (e.g. GIULIANI 2007) that clusters do not necessarily exhibit a cohesive local network of collective learning, this paper addresses the question under which conditions these networks emerge within clusters. By doing a longitudinal case study of the cluster of Sophia-Antipolis, this study aims to shed light on the question how differences in the evolution path of spatial clustering can have implications for the evolution of local networks of collective learning. In order to do so, this paper presented a longitudinal case study of the cluster of Sophia-Antipolis at the French Côte-d'Azur in which the co-evolution of spatial clustering and networks of collective learning were reconstructed.

Sophia-Antipolis is one of the archetypes of successful European high-tech clusters that to a large extent have been created artificially. Through the course of time the cluster has progressively specialized towards Information Technology and, to a lesser extent, Life Sciences. Whereas the growth of firms in Information Technology has become stronger based on local spin-offs and high-tech start-ups from the early 1990s, the Life Sciences Sector in Sophia-Antipolis does not grow any longer and is still dominated by relatively large subsidiaries of multinational firms.

On the basis of a longitudinal analysis of patent-based networks this paper has shown that Information Technology and Life Sciences strongly differ in the way in which their networks of individual inventors evolved over time. Throughout the emergence and growth of the business park a slight trend towards the emergence of collective learning could be observed in

1  
2  
3 Information Technology. Even though the network of inventors remains fairly  
4  
5 fragmented, the decrease in average path length signalled the emergence of  
6  
7 a more coherent local network over time, in which shortcuts exist that interlink  
8  
9 dense subgroups of the network across the business park. It is argued that  
10  
11 the shift towards growth based on local spin-offs and high-tech start-ups in  
12  
13 Information Technology has been an important factor that enabled these  
14  
15 developments. Inventors from spin-off and start-up firms might perform a key  
16  
17 role in interconnecting inventors across organizational and disciplinary  
18  
19 boundaries. By contrast, in Life Science no trend towards the emergence of a  
20  
21 local collective learning milieu could be observed. The inventor network has  
22  
23 always been strongly outward oriented, highly fragmented, with long path  
24  
25 lengths and low clustering coefficients. Likewise, the absence of local spin-off  
26  
27 and start-up firms in Life Sciences might have been a key obstacle for the  
28  
29 emergence of a collective learning milieu in Life Sciences.  
30  
31  
32  
33  
34  
35

36 These outcomes have two important implications. First, the outcomes  
37  
38 of this study suggest that the extent to and the way in which firms get  
39  
40 concentrated locally highly affect the structure of the local inventor network in  
41  
42 a cluster. The absence of any detectable form of local collective learning in  
43  
44 Life Sciences demonstrates that geographical proximity is not a sufficient  
45  
46 condition for local collective learning to take place. In IT, the bigger total  
47  
48 concentration of firms and the locally-based nature of its growth in more  
49  
50 recent years appear to have been necessary conditions for local collective  
51  
52 learning to emerge. The results suggest that high-tech start-ups and spin-off  
53  
54 firms play an important role in establishing local collective learning.

Second, this study demonstrates the emergence of a local collective learning milieu is a very incremental and long-lasting process, which in the case of Information Technology in Sophia-Antipolis has taken about 20 years. It has only been since the growth regime changed from the being the result of newly arriving foreign multinationals to a growth mainly based on local spin-offs and high-tech start-ups in the early 1990s that collective learning practices started to emerge. And even then the local network of collective learning remains fairly fragmented; it is evident that the potential for local collective learning in Information Technology still is far from being exhausted.

#### ACKNOWLEDGEMENTS

I would like to thank the VolkswagenStiftung for funding this research. Special thanks go to Loïc Coutures for his assistance during the interviews and to Jean-Luc Gaffard for hosting me for several months at the OFCE-DRIC in Sophia-Antipolis. Furthermore I would like to thank Ron Boschma, Koen Frenken, and Michel Quéré for their supervision and helpful suggestions to earlier versions of the paper. This paper has greatly benefitted from being presented at workshops of the DIME Working Package 2.3.

## Appendix 1: allocation of EPO patents to industries

The Concordance Table as developed by Schmoch et al. (2003) was used in order to allocate EPO patents to Information Technology, Life Sciences or Miscellaneous. The following technological fields have been assigned to Information Technology: 12 Audiovisual Technology, 13 Telecommunications, 14 Information Technology, 15 Semiconductors, 22 Analysis, measurement and control technology.

The following technological fields have been assigned to Life Sciences: 23 Instruments – Medical Technology, 31 Organic fine chemistry, 32 Macromolecular chemistry and polymers, 33 Life Sciences, cosmetics, 34 Biotechnology, 35 Agriculture and food chemistry, 36 Chemical industry, petrol industry and basic materials chemistry.

## Appendix 2: allocation of USPTO patents to industries

The subcategories as defined by Hall et al. (2001) were used in order to allocate USPTO patents to Information Technology, Life Sciences or Miscellaneous. The following sub-categories have been assigned to Information Technology: 2 Computer and Communications (including Communications, Hardware and Software, Computer Peripherals and Information Storage) and 4 Electrical and Electronic (including Electrical Devices, Measuring and Testing, Power Systems and Semiconductor Devices).

1  
2  
3 The following sub-categories have been assigned to Life Sciences: 1  
4  
5 Chemical (including Agriculture, Food, Textiles; Coating; Gas; Organic  
6

<sup>i</sup> Department of Economic Development at the Regional Council (Conseil Général Alpes-Maritimes), Syndicat SAM, Team Côte d'Azur, Fondation Sophia-Antipolis.

<sup>ii</sup> INRIA (The French National Institute for Research in Computer Science and Control), Eurécom (a private research centre in communication systems), Ecole des Mines de Paris (Paris Institute of Technology), Nice Sophia-Antipolis University, INRA (French National Institute for Agricultural Research) refused cooperation.

<sup>iii</sup> The Path Length ratio is the average path length in the actual network over the expected path length in a random network of equal size and density. The actual path length is calculated as the average geodesic distance between all dyads in the network. For calculating the random expected path length the bipartite (two-mode) nature of the network needs to be taken into account. Instead of using the average degree and the number of nodes in the network (as one would do in a one-mode network) one utilizes the number of inventors per patent ( $\mu$ ) and the number of patents per inventor ( $\nu$ ) to approximate the random expected path length.

<sup>iv</sup> Again, the bipartite nature of the inventor network has implications for the way in which the actual and expected values of the clustering coefficient are calculated. Since all inventors that have worked together on a patent form a fully connected clique, the clustering coefficient is by definition much higher than in a one-mode network. Similar to the expected random path length, the random clustering coefficient takes the average number of inventors per patent ( $\mu$ ) and the average number of patents per inventor ( $\nu$ ) into account. It is assumed that both  $\mu$  and  $\nu$  follow a Poisson-distribution.

<sup>v</sup> Establishments include firms (both SMEs and subsidiaries of multinationals), research institutes and universities.
