Running head: Recollections of exhibits

Recollections of Exhibits:

Stimulated Recall Interviews With Primary School Children About Science Centre Visits

For Peer Review Only

Abstract

One issue of interest to practitioners and researchers in science centres concerns what meanings visitors are making from their interactions with exhibits and how they make sense of these experiences. The research reported in this study is an exploratory attempt, therefore, to investigate this process by using video clips and still photographs of schoolchildren's interactions with science centre exhibits. These stimuli were used to facilitate reflection about those interactions in follow-up interviews. The data for this study were 63 small group interviews with UK primary school children (129 students, ages 9-11). Interviews were transcribed and then analysed for common themes. The analysis presented here explores how students explain or interpret particular exhibits and the extent to which they were cognitively engaged by the process of observing their interactions with exhibits. The findings show that digital media enable students to revisit their experience and engage them with the content underlying science centre exhibits. There was, however, little difference between the patterns of response stimulated by video as opposed to photographs. It seems that such 'revisitations' of exhibit interactions could serve as a valuable means of developing further students' scientific concepts and exploiting the value for learning from the experience afforded by informal contexts.

Recollections of Exhibits:

Stimulated Recall Interviews With Primary School Children About Science Centre Visits

One issue of interest to both practitioners and researchers in museums and science centres is what meanings visitors are making from their interactions with exhibits and how they make sense of these experiences. Understanding how exhibits¹ are interpreted by visitors could provide guidance for possible improvements and could also highlight ways interactions could be utilised to extend the experience of the visit.

Evidence suggests that interactions with exhibits can have a memorable impact on visitors (Falk et al., 2004; Rennie, 2007; Stevenson, 1991; Tulley & Lucas, 1991). For instance, Stevenson (1991) found that adult and child visitors were able to recall exhibits they had seen or experienced during a science centre visit up to six months after and, in a study conducted by Falk et al. (2004), adult visitors not only remembered the visit itself six months later but could also articulate the impression or impact it had made upon them. Moreover, years of research conducted in science centre settings affirms that visits – whether in family groups or on school trips – are not only remembered but also have the potential to generate both cognitive and affective outcomes (Anderson & Lucas, 1997; Bamberger & Tal, 2007, 2008; Borun et al., 1997; Falk & Dierking, 2000; Hein, 1998; Jarvis & Pell, 2002, 2005; Leinhardt, Crowley, & Knutson, 2002; Orion & Hofstein, 1994). In addition, research has found that such outcomes – particularly cognitive – can be strengthened by reinforcing experiences, such as follow-up activities in the classroom (c.f., Anderson, 1999; Anderson et al., 2000; Farmer & Wott, 1995).

1
2
3 A review of this body of research reflects that much of it has focused traditionally on
4 learning outcomes (DeWitt & Storksdieck, 2008; Falk & Dierking, 1992; Rahm, 2004), but
5 more recently, research has also begun to examine more closely the *processes* of meaning
6 making, with a particular emphasis on conversations that occur during visits (e.g., Ash, 2003;
7 Leinhardt, Crowley, & Knutson, 2002). However, there still seems to be relatively limited
8 work exploring visitors' – especially children's – perspective on exhibits, on how they
9 interpret or explain exhibits and their interactions with them. In one example, Tuckey (1992a)
10 asked children aged 8 to 11 to explain the function and purpose of exhibits during their visits
11 to an interactive science centre. She found that they often drew on their previous knowledge
12 and experience, although the depth and accuracy of their explanations varied considerably.
13 Questionnaires filled out a week later revealed that older children seemed to have some
14 degree of understanding about the underlying principles, while younger children tended to
15 give simpler descriptions of what they had observed (Tuckey, 1992b). However, these data
16 did not reveal what resources or conceptions they brought to bear on understanding or
17 interpreting the exhibits and provided only limited insight into the sense students made of the
18 exhibits. Moreover, this study only investigated children's understanding and memories
19 shortly after the visit, leaving open the question about what the longer-term impressions of the
20 visit might be. Apart from the work of Stevenson (1991) and Falk and his colleagues (2004),
21 most research exploring how visitors, especially children, interpret or explain interactive
22 exhibits has been conducted either during the visit, or shortly after (e.g., Feher & Rice, 1985).

23

39
40
41
42
43
44
45
46
47
48
49
50
51 Nevertheless, the field of research on learning in informal settings is not only
52 interested in the sense visitors make of their experiences at the time, but also how their
53 interpretations may change over time. Falk and his colleagues (2004) interviewed visitors to a
54 science centre immediately following their visit as well as four to six months later. Analysis
55 of visitors' responses about what they learned from particular exhibits indicated limited
56
57
58
59
60

1
2
3 correlations between short-term and long-term outcomes, suggesting that the impact of the
4
5 visit may shift over time.
6
7

8 The possibility that the impact of a science centre visit, or of exhibit interactions, may
9
10 change over time, as well as ongoing questions about the nature of longer-term impacts of
11
12 these experiences, has led us to ask how visitor recollections might be explored in more detail.
13
14 One promising method involves using the technique of stimulated recall in follow-up
15
16 interviews. With this method interviewees, such as museum visitors, are shown photos from a
17
18 setting, such as an exhibition, with the intention of facilitating recall and reflection on the
19
20 experience. Such techniques have been used in previous research on learning from visits to
21
22 zoos (Tofield et al., 2003) and science centres (Stevenson, 1991). In his research Stevenson
23
24 (1991) used photos of exhibits in interviews conducted approximately six months after a visit
25
26 to an interactive science centre. This study indicated that stimulated recall techniques were
27
28 effective in prompting recall about the experience, though most of visitors' memories were
29
30 fairly straightforward accounts of what happened during the exhibit interaction. Memories
31
32 indicating further reflection were less frequent.
33
34
35
36
37

38 However, trips to science centres are busy, active experiences and any still photograph
39
40 will fail to capture the dynamic nature of exhibit interactions. Video has a greater capability
41
42 than static photographs to capture the range and sequence of actions that occur during
43
44 interactions with science centre exhibits. Therefore, stimulated recall techniques using video
45
46 may prove more effective than photographs in prompting recall and reflection on these kinds
47
48 of experiences. Indeed, video has been found to be effective in encouraging adults and
49
50 children to reflect on their interactions with science centre exhibits immediately after the
51
52 experience (Falcao & Gilbert, 2005; Stevens & Hall, 1997; Stevens & Martell, 2003). Other
53
54 researchers have used it as a tool to help secondary school students re-visit and reflect on their
55
56 learning processes following an amusement park excursion with a physics focus (Anderson &
57
58
59
60

1
2
3 Nashon, 2007). However, previous studies of science centre visits that have used video have
4
5 not focused on school trips or have worked with only very small numbers of school children,
6
7 despite the popularity of science centres as field trip destinations.
8
9

10
11 Given this evidence suggesting the potential of video to encourage a 're-engagement'
12
13 with prior experience (Anderson & Nashon, 2007; Falcao & Gilbert, 2005; Stevens & Hall,
14
15 1997), the question for us was what potential value did it offer for science centre visits? A
16
17 particular focus was whether video might offer more promise in encouraging school children
18
19 to reflect on their interactions with exhibits – that is why they did what they did and/or what
20
21 they think an exhibit shows – than did the static photos used in previous research (e.g.,
22
23 Stevenson, 1991). Such reflections, in turn, may provide valuable insights into the nature of
24
25 their experience and into the meanings they are making from their interactions. They may
26
27 even provide some insight into the processes by which students make meaning – or the
28
29 resources they bring to bear in interpreting exhibits. Consequently, the research reported here
30
31 seeks to extend and build on previous work by using video clips of school children's
32
33 interactions with selected science centre exhibits to facilitate their reflection about those
34
35 interactions in follow-up interviews – an approach which has not been used elsewhere, other
36
37 than in a very small pilot study (Falcao & Gilbert, 2005) and then only immediately after a
38
39 visit. Insight into students' meaning making about exhibits may also potentially highlight new
40
41 ways to reinforce and enhance learning from these experiences.
42
43
44
45
46
47

48
49 It should be noted that the questions explored in this research focus first and foremost
50
51 on students' cognitive engagement with exhibits and how they make meaning of their
52
53 experiences. More specifically, this paper will attempt to explore how students explain or
54
55 interpret particular exhibits and the extent to which they draw on or elaborate concepts in the
56
57 process. This is not to say that there are not social and affective dimensions to their exhibit
58
59 interactions and their science centre trip – elements of which are reported here. However, the
60

1
2
3 primary focus of this work was on the potential of video to encourage reflection and cognitive
4
5 engagement, as this seems to offer more possibilities of supporting and extending conceptual
6
7 learning afforded by the children's interactions with science centre exhibits.
8
9

10 Research Design and Data Collection

11
12 In order to explore how they interpreted their experiences, video recordings and still
13
14 photographs were taken of students interacting with selected exhibits during their school trips
15
16 to a science centre in the United Kingdom, and these photos and video were later used as
17
18 stimuli to prompt their recall in interviews. The science centre was housed in a dedicated
19
20 modern, purpose-built building and contained a wide range of exhibits typical of many
21
22 science centres. The 'target' exhibits included in this study were ones which the researchers
23
24 could be reasonably certain the students would visit and also permitted filming (i.e., were
25
26 sufficiently well-lit). Most school trips to this science centre are focused on particular themes
27
28 (e.g., Forces), which connect to topics in the National Curriculum for England and Wales.
29
30 During their visits, students are given a paper-based worksheet or 'trail' of five thematically-
31
32 related exhibits to explore while they are on the exhibit floor, and the 'target' exhibits (where
33
34 filming took place) were selected from this trail. However, the order in which they visit the
35
36 exhibits and their timing was under the control of the students, and students had ample time to
37
38 visit exhibits not on the trail.
39
40
41
42
43
44

45
46 Students from upper primary classes (ages 9-11) from five schools participated in the
47
48 research, representing a convenience sample of schools already scheduled to visit this centre.
49
50 This was not seen as a limitation as the basic design of this study was exploratory – an
51
52 attempt to investigate the potential value of such a methodological approach². Exploring new
53
54 methods is important, as one of the challenges facing the field is to establish good methods for
55
56 collecting valid and reliable data about what happens during visits to science centres and
57
58 possible learning outcomes (Osborne & Dillon, 2007). All five schools were publicly-funded
59
60

1
2
3 and located in suburban areas or small towns. All students for whom consent had been
4
5 obtained, which was the majority of students in each class, were interviewed following their
6
7 trips. The interviews were conducted at the schools, using both video clips and still
8
9 photographs as a prompt to reflection. Both types of stimuli were included to test the
10
11 possibility that the dynamic medium of video would be more effective than static photographs
12
13 at stimulating recall and cognitive activation.
14
15

16
17 Students were interviewed in pairs or groups of three because it was felt that they were
18
19 likely to be more comfortable being interviewed with a peer than on their own and that the
20
21 opportunity for peer interaction may stimulate more extensive discourse and elaborated recall.
22
23 In addition, this research takes a sociocultural perspective on learning, which holds that
24
25 knowledge is constructed via discourse, in interactions among individuals (Wells, 1999; Wells
26
27 & Claxton, 2002), and the actions of the individual, the social environment and their
28
29 interaction all form an inseparable whole. Interviewing students in pairs or threes facilitated
30
31 social interactions within the context of the interview which, in turn, might have helped
32
33 students to mutually reconstruct their knowledge and potentially stimulated more extensive
34
35 recall of their visit. Or, to put it another way, the context of the interview replicated the
36
37 context of the visit where students explored exhibits predominantly with their peers and
38
39 possibly enhanced their recall of that experience.
40
41
42
43
44

45
46 The pairs (or groups of three) in the interviews consisted of peers who had explored
47
48 the exhibits together. In total, 129 students from the five schools participated in 63 interviews,
49
50 in which they were shown a combination of video clips and still photographs of themselves at
51
52 the target exhibits. As shown below, the target exhibits varied with the theme of the visit. In
53
54 most interviews, students would see a photograph (or photographs) taken at one target exhibit
55
56 and a video clip (or clips) recorded at another. If there were three target exhibits for that class,
57
58 the stimulus for the third could be of either type. Occasionally, students saw only video clips
59
60

1
2
3 or photographs, depending upon what had been recorded during their visit, which was
4
5 sometimes limited by technical difficulties with the equipment. However, attempts were made
6
7 to balance roughly whether photos or videos were shown for each exhibit across interviews.
8
9 The details of the sample, the theme (or focus) of the visit, and the timing of the interviews
10
11 are summarised in Table 1.
12
13

14
15
16
17 --- Insert Table 1 about here ---
18
19
20
21

22 The interview protocols used were developed to explore the cognitive and affective
23
24 elements of students' interactions with the exhibits, as well as the visit overall. To gain initial
25
26 insight into students' perspectives on their exhibit interactions, they were first asked questions
27
28 about what was happening in the clip or photo and how the exhibit 'worked'. To explore
29
30 cognitive learning outcomes more specifically, students were also asked to discuss what they
31
32 learned from the experience and what they thought the purpose of the exhibit was (e.g., 'What
33
34 do you think this exhibit is trying to show you?'). The interviews also addressed affective
35
36 outcomes, using questions about whether or not students had enjoyed each exhibit they were
37
38 shown (in a photo or video) and why. Students were not restricted to discussing solely the
39
40 'target' exhibits, and during the course of their interviews most students referred to additional
41
42 exhibits (which did not appear in a video or photo) they had interacted with during their visits.
43
44 Finally, students were asked to rate how interesting they had found the visit overall and to
45
46 justify these ratings. [The interview protocol is available from the authors.](#)
47
48
49
50
51
52

53 The qualitative and essentially exploratory nature of this study permitted a degree of
54
55 flexibility in its design. As Table 1 shows, the participating classes did not have the same
56
57 'target' exhibits – these varied depending on the theme of the visit. (A description of the
58
59 exhibits is found in Appendix 1.) Such a design had the added advantage of allowing the visits
60

1
2
3 to be experienced with a minimum of disruption, in that students were not asked to do
4
5 anything different from what they would have done normally. Students from two schools
6
7 were interviewed the week following their visit, but those from the remaining three were
8
9 interviewed ten to twelve weeks later (after an intervening summer holiday) in order to
10
11 explore possible differences in recall and reflection over different time periods.
12
13

14
15 It should also be noted that teachers reported undertaking minimal preparation and no
16
17 specific follow up to these visits. Given this, it is also unlikely that students were encouraged
18
19 to discuss or reflect upon the visit prior to the interviews, with the possible exception of
20
21 students from Chestnut School, whose visit had the 'Living in Space' theme (or focus) and
22
23 occurred at the beginning of a short classroom unit about space.
24
25

26 27 Coding and Analysis

28
29 All interviews with students were transcribed, and a coding schema was developed
30
31 and refined in an iterative process, in which categories emerged from the data (Lincoln &
32
33 Guba, 1985). An extensive coding schema was utilised, although the current discussion
34
35 focuses primarily on findings corresponding to the cognitive dimension of students'
36
37 responses. 'Cognitive' codes ranged from statements about how the exhibits functioned, to
38
39 descriptions of the phenomena that were observed, to their understanding of the underlying
40
41 scientific principles that the exhibits demonstrated. Further sets of codes were developed in
42
43 order to capture the affective dimensions of students' interactions with exhibits and responses
44
45 to the visit overall. Affective codes were generally used to categorise students' reasons for
46
47 considering exhibits as enjoyable, fun or interesting, such as the fact that an exhibit was
48
49 challenging or allowed for hands-on interaction. [A list of all code definitions is available from](#)
50
51 [the authors](#). In addition, transcripts were also coded to indicate whether students were
52
53 referring to a photo or a video at any given point, so that any differences in their responses
54
55 based on the type of stimulus could be noted.
56
57
58
59
60

1
2
3 The transcripts themselves were coded using the NVIVO software package, which
4 permits a picture of the frequency of code use to emerge. However, while it is of interest to
5 explore what kinds of statements students seemed to be making most frequently when
6 describing their interactions with exhibits, the analyses also note whether particular codes,
7 such as ‘science conception’, appeared at all in the interview.
8
9
10
11
12
13
14

15 Findings

17 *Eliciting Cognitive Response*

18
19 The codes used to capture the cognitive dimension of students’ reflections, or their
20 cognitive engagement with the content of the video or photo and with the phenomena
21 displayed by these stimuli, were:
22
23
24
25

- 26 • exhibit appearance (visual descriptions of exhibit appearance or ‘what it looks like’),
 - 27 • student action (students’ physical interactions with an exhibit),
 - 28 • observed phenomenon (phenomena that were demonstrated or ‘what happened’),
 - 29 • fact (discrete factual statement, generally a property or process),
 - 30 • exhibit-focused fact (similar to ‘fact’ but more closely tied to the exhibit),
 - 31 • causal (causal explanation),
 - 32 • science skill (e.g. comparing, classifying) and
 - 33 • science conception (attempts to use understanding of scientific concept).
- 34
35
36
37
38
39
40
41
42
43
44
45

46 A Piagetian analysis would suggest that the order of the scheme represents, roughly,
47 increasing levels of abstraction from that which students could observe visually and
48 experience physically at the exhibit towards more cognitive engagement or reflection on the
49 underlying content of the exhibit. Table 2 summarises the frequency with which these codes
50 were applied to students’ interview transcripts.
51
52
53
54
55
56
57
58
59
60

--- Insert Table 2 about here ---

1
2
3
4
5
6 Because the codes could be applied to statements of varying length (and because of
7
8 the semi-structured nature of the interviews, in which students talked to varying degrees),
9
10 statistical analyses of the data are inappropriate. Nevertheless, frequency counts of the data do
11
12 provide the broad features of their post-hoc reflection. It would seem that the majority of
13
14 statements made by students when discussing their interactions with exhibits and what they
15
16 found out from those experiences were fairly straightforward descriptions of the exhibits'
17
18 appearance or observable features (*exhibit appearance*), of what they did physically with the
19
20 exhibits (*student action*) and, especially, of the phenomena that were observed (*observed*
21
22 *phenomenon*). In addition, this pattern generally held whether video clips or still photographs
23
24 were used as stimuli (Table 3) and whether interviews were conducted shortly after the visit
25
26 or following an interval of 10-12 weeks (Table 4).
27
28
29
30
31
32
33

34 --- Insert Table 3 about here ---
35
36
37
38

39 --- Insert Table 4 about here ---
40
41
42

43 Thus, as the two samples are similar in the general pattern of codes they produce,
44
45 further discussion of these findings will draw on all student interviews as the data source in
46
47 the sections that follow. It is also inappropriate to make a statistical comparison of the number
48
49 of comments made by students when looking at photos as compared to video clips, as the
50
51 length of the video clips varied, and students sometimes saw more than a single photo of
52
53 themselves at an exhibit.
54
55
56
57
58
59
60

1
2
3 We now turn to discuss the major features emerging from this aspect of the coding,
4
5 namely statements about what was readily perceptible, statements that indicated further
6
7 cognitive engagement, and statements utilising students' prior knowledge.
8
9

10 *Readily Perceptible.* As can be observed from the tables, comments about what
11
12 exhibits looked like (coded *exhibit appearance*) were one of the most frequent kinds of
13
14 statements and included descriptions such as: 'There's four of those balls' (*Chestnut School,*
15
16 *Orbits*) and 'There's this big triangle thing and the air' (*Sugaroak School, Bernoulli Blower*).
17
18 (For a description of exhibits, please see Appendix 1.)
19
20
21

22 While the above statements simply named what could be noticed visually about the
23
24 exhibit itself, other statements (coded *student action*) described what students did physically
25
26 in interacting with an exhibit – effectively, how to make it 'work'. Examples include: 'You
27
28 pull a rope, yeah' (*Leaf School, Heave Ho*) and 'We've taken it in turns to spin the thing and
29
30 then we was pressing the button' (*Redwood School, Hydrogen Rocket*).
31
32
33

34 Although the above two types of statements (*exhibit appearance* and *student action*)
35
36 were made quite often by students when discussing exhibits, statements in which students
37
38 described what they had observed at the exhibit – or what had 'happened' (coded *observed*
39
40 *phenomenon*) – tended to appear most frequently in the transcripts, regardless of the type of
41
42 stimuli used (photo or video), the exhibit being described and whether the interview occurred
43
44 shortly after the visit or weeks later. In addition, such statements appeared at least once – and
45
46 generally considerably more often – in every interview conducted. Typical examples were:
47
48
49
50
51
52

53 It floats and goes up and down with your hands. It's like you're pushing it,
54
55 but without touching it. *Sugaroak School, Bernoulli Blower*
56
57
58
59
60

1
2
3 It (the cork) shot up nearly all the way to the top and then came back down.
4

5 *Chestnut School, Hydrogen Rocket*
6
7

8
9
10 It went for ages. It started doing the circles, and then as it slowed down it
11
12 began doing the 8 shape. *Redwood School, Orbits*
13
14

15
16
17 When you get it started it goes quite fast, and then when you try and stop
18
19 it, it's really hard. *Sugaroak School, Kugel*
20
21

22
23
24 While such statements are fairly straightforward descriptions of what happened at the
25 exhibits, the fact that it was such features that were recalled indicates that students are going
26 beyond a simple ontological description of its elements and can recall a sequence of events,
27 some of which were not actually visible in the stimuli on which they were commenting.
28
29

30
31
32 *Further Cognitive Engagement.* Despite the perceptual nature of most of the
33 statements students made when discussing their interactions with exhibits, some students did
34 spontaneously make statements that seemed to be further removed from what was
35 immediately perceptible. For instance, when asked what he would tell a friend that an exhibit
36 is 'showing', one student replied, 'That air can hold quite light balls in one sort of place'
37 (*Sugaroak School, Bernoulli Blower*). Our view is that this sentence is more generalised in
38 that it describes what air can do – this student having arrived at some sort of conclusion about
39 a property of air, rather than simply stating what he observed while interacting with the
40 exhibit.
41
42
43
44
45
46
47
48
49
50
51
52
53

54
55 In response to a similar question about what he had learned at Orbits, a student from
56 another school responded, 'Balls can't go in holes when it's all bendy' (*Chestnut School*).
57
58 Whilst such a statement contributes little to understanding the concept and idea underlying the
59
60

1
2
3 exhibit, it does demonstrate an attempt to construct a generalised explanation and to go
4
5 beyond the phenomenon itself. Speaking about the Bubble Race exhibit, another student
6
7 explained that he found out that 'Air bubbles move faster through thinner liquids than thicker
8
9 liquids' (*Leaf School, Bubble Race*). And similar types of statements were made about other
10
11 exhibits, such as: 'Different pulleys can make it easier or harder to pull up six kilograms'
12
13 (*Leaf School, Heave Ho*) and 'Water can make things easier to push' (*Sugaroak School,*
14
15 *Kugel*).
16
17
18

19
20 The above statements suggest that students were attempting to extract the underlying
21
22 properties or characteristics of balls and surfaces, of air bubbles and liquids, and of pulleys
23
24 and water. In all cases, this is a process that requires the ability to see beyond the descriptive
25
26 and a willingness to construct models of physical systems – features which suggest a greater
27
28 degree of cognitive engagement and reflection on their experience than just descriptive
29
30 accounts of what the exhibit is or what it does. As Table 5 shows, statements coded as *Fact* or
31
32 *Exhibit-focused fact*, while certainly less frequent than descriptions of the phenomena that
33
34 were observed, appeared at least once in 90% (57 of 63) of the interviews, suggesting that
35
36 stimulated recall techniques can prompt this greater level of generalisation or distance from
37
38 what is immediately perceptible. That such statements were elicited also highlights the
39
40 importance of scaffolding in order to make the most of these types of experiences. Unless
41
42 students are scaffolded to transcend the simple ontological questions of what the exhibit is or
43
44 what it does, to ask the causal question of how it works or the more general question of what
45
46 it shows, it is doubtful if the full educational experience of the interaction – and the visit –
47
48 will be exploited.
49
50
51
52
53
54
55
56
57
58
59
60

--- Insert Table 5 about here ---

1
2
3 Cognitive engagement with what can be observed at an exhibit is also suggested by
4 statements in which students attempted to provide a *causal explanation* for what they see. For
5 instance, one student noted that the Kugel (a big granite ball resting on a thin film of water)
6 was very hard to stop once it was spinning. In describing what happened, he explained that it
7 was the water making it hard to stop 'because it's slippery.' (*Sugaroak School*). A classmate
8 explained the same phenomenon by saying, 'You couldn't stop it because the water was
9 underneath and still pushing it' (*Sugaroak School*).
10
11
12
13
14
15
16
17
18
19

20 Thus, revisiting the experience in an interview has stimulated the construction of an
21 explanation, albeit scientifically incorrect. Likewise, students from another school tried to
22 explain why one of the bags in Heave Ho felt heavier:
23
24
25
26
27
28

29 S1: That one's easiest.

30 S2: Because it has more pulley-things. (*Leaf School*)
31
32
33
34
35

36 While the above statement does not articulate *how* pulleys make something more
37 difficult or easier to pull, it does indicate an attempt to describe the cause of what was
38 observed. Other students provided more detailed causal explanations of observed phenomena,
39 although these were not always correct. In the following excerpt, a student attempted to
40 explain why the cork goes up in the Hydrogen Rocket exhibit:
41
42
43
44
45
46
47
48
49

50 I think it's like air pressure. And as it builds up inside that chamber then
51 it... it kind of sucks up all the air pressure. And then it lets it out into the
52 rocket shaped thing, and then that pushes up a cork and makes it go up.
53
54
55
56

57 (*Redwood School*)
58
59
60

1
2
3 A student from another school provided a different, also incorrect, explanation: 'Water
4 – it got bubbles into it a bit and they pushed it – and it would go really higher' (*Chestnut*
5
6
7
8 *School*).

9
10 Although statements such as these were not as frequent as the observations
11 themselves, that 12% of cognitive statements did reflect attempts to provide some sort of
12 causal explanation for an observed phenomenon would seem to be noteworthy. The
13 appearance of such statements shows the potential that re-visiting exhibit interactions afford
14 as a means of encouraging students to think more deeply about what has been observed and to
15 begin to construct explanatory models – something which is central to the nature of science
16 itself. Moreover, students made this kind of statement in 94% (59 of 63) of interviews and
17 such statements occurred in the context of interviews which primarily attempted to elicit what
18 students might remember about their science centre visits. It remains an open question how
19 much better teaching and learning experiences which attempted specifically to exploit the
20 potential of such nascent memories for learning science might be.
21
22
23
24
25
26
27
28
29
30
31
32
33
34
35

36 *Using Prior Knowledge.* Finally, some students not only tried to provide causal
37 explanations for what they observed, but went a stage further by attempting to bring their
38 existing science conceptions or understandings to bear as they tried to interpret, explain, or
39 make sense of interactive exhibits. For instance, in describing what the Bernoulli Blower was
40 attempting to show, one student explained, 'It's, like, overpowering, well, it's not
41 overpowering gravity, but it equals gravity. So, it's the up-thrust, it was gravity, so it lets it
42 float.' He then went on to state: 'You can equal, like, the force of gravity with another force –
43 usually you can't just make a ball float in the air' (*Leaf School*). This student did have some
44 difficulty in articulating his interpretation of the exhibit (which is not entirely accurate).
45
46
47
48
49
50
51
52
53
54
55
56
57 Nevertheless, he attempted to apply the scientific concepts of force and gravity (or his
58 understanding of them) as he tried to explain what he had observed.
59
60

1
2
3 Another student also referred to gravity as she attempted to explain Heave Ho: 'I think
4 probably what I learnt from it was that it was probably showing us that probably the heavier a
5 thing is, the greater gravity pulls down on it' (*Leaf School*). In this case the student missed the
6 point of the exhibit and may not have noticed the pulleys at all. However, she had noticed that
7 different bags seemed to weigh different amounts (in that some were easier or harder to lift)
8 and attempted to draw upon a familiar science concept she connected with weight – gravity.
9 Later statements reflected that her understanding of gravity was not as sophisticated or
10 accurate as the above comment might suggest, but the important point here is that it
11 demonstrates an attempt to utilise her science knowledge to explain what she has observed.
12
13
14
15
16
17
18
19
20
21
22
23

24 In describing what they learned from their interactions with the exhibit Kugel, students
25 from another school also referred to science concepts:
26
27
28
29
30

31 S1: Trying to stop it, it's like friction with the water and the ball in your
32 hands.
33

34 S2: It's like water pressure a bit, but not. Well, you're trying to push it
35 and the water's moving it... making you not, cos it's getting
36 slippery. (*Sugaroak School*)
37
38
39
40
41
42
43
44
45

46 The second comment, in particular, illustrates the student drawing on his
47 understanding of a range of science concepts, as he struggled to find the term that would
48 adequately explain what he had observed.
49
50
51

52 In another instance, two students refer to gravity, as well as thrust, in attempting to
53 explain Hydrogen Rocket:
54
55
56

57 S1: It's like the rocket going up in space.
58
59
60

1
2
3 S2: Yeah, because when it goes up, it's really hard because you need all
4
5 them rocket fuel and all that to burn and the thrust to push it up.
6
7

8 S1: Because the thrust pushes the rocket up. And when it gets up...

9
10 S2: Well, it sucks it down again.
11

12 S1: Yeah, because of the gravity. (*Chestnut School*)
13
14
15
16

17 Although such statements did not appear frequently in the transcripts, that they
18 occurred at all is of interest because they highlight the way in which students were attempting
19 to make sense of their experiences in the visit by drawing on their existing understanding of
20 scientific concepts. That these '*science conception*' statements appeared at least once in 83%
21 (52 of 63) of the interviews again indicates the potential of utilising stimulated recall in
22 interviews to encourage reflection on underlying science principles. From a constructivist
23 perspective (Hein, 1995; Osborne & Wittrock, 1985), such a finding is also not surprising as it
24 illustrates children attempting to make sense of the unfamiliar in terms of their pre-existing
25 concepts. It also reinforces the importance of science centres utilising students' common
26 conceptual frameworks – that is, the ideas they are likely to be familiar with from school and
27 everyday life – as a starting point from which they can help students develop their knowledge
28 and understanding from their visit experiences.
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44

45 We do not suggest that students would have spontaneously reflected on these exhibits,
46 either during the visit or subsequently, nor that they would utilise their existing science
47 understandings without being prompted. Nevertheless, the interviews do provide evidence,
48 consistent with previous research (e.g., Stevens & Hall, 1997; Stevens & Martell, 2003) that
49 interactions with science centre exhibits can provide opportunities for reflection and deeper
50 engagement with science concepts and processes after the visit itself, even after considerable
51 delay. Such reflection and engagement can serve as building blocks for the development of
52
53
54
55
56
57
58
59
60

1
2
3 future understandings. Moreover, that using video (or photos) to re-visit these experiences
4
5 following a school trip can be cognitively demanding suggests that there is educational value
6
7 to incorporating such media in follow-up activities, a practice that teachers may find relatively
8
9 easy to implement, given how many take photos or even video during school trips (Kisiel,
10
11 2006).
12
13

14
15 *Students' Views of the Function and Purpose of Exhibits.* The interview data not only
16
17 provided evidence of the way in which re-visiting their exhibit interactions could engage
18
19 students with underlying science content, but also showed that students seemed to view the
20
21 visit as a 'learning experience' – they were often able to articulate answers to questions about
22
23 what they thought particular exhibits were supposed to show. Their interpretations were not
24
25 always correct, indeed rarely so, but students clearly seemed to appreciate – and expect – that
26
27 the exhibits they encountered had a purpose, generally related to science. For instance, when
28
29 asked about the purpose of Hydrogen Rocket, students responded:
30
31
32
33
34
35

36 S1: It's to show how high it can go.

37
38 S2: It's showing the power and the electricity and mixing the liquids, so like
39
40 science, all part of science. (*Chestnut School*)
41
42
43
44
45

46 That students did connect these experiences with learning science is not only reflected
47
48 by the purposes they ascribed to the exhibits and their attempts to utilise existing science
49
50 understandings to interpret observed phenomena, but is also suggested by their frequent use of
51
52 science terminology (such as *gravity*, *friction*, and *pressure*). Nearly all students used such
53
54 terms as they talked about exhibits they had encountered during their visits, with these terms
55
56 appearing in 87% of interviews. Some students, albeit fewer, even described how they used
57
58 science skills – such as fair testing – in their exhibit interactions. For instance, in discussing
59
60

1
2
3 what he had done at the Bubble Race exhibit, one student said, 'But to make it a fair test, you
4 have to wait until they [bubbles] were all equal at the bottom' (*Leaf School, Bubble Race*).

5
6
7 Another reported, 'I did a big spin. And I did it twice to make the test fair. Because, like, if
8 you did it once and you didn't exactly get the right answer, do it again to make it get the right
9 answer, if it is the right answer' (*Leaf School, Bubble Race*).

10
11
12
13
14
15 Nevertheless, although students at various times used scientific terminology, referred
16 to science process skills and drew upon their prior science knowledge in the interviews, they
17 rarely made connections explicitly to what they had learned in school.

18
19
20
21
22 *Stimulus Type and Interview Timing.* As Table 3 reflects, the patterns of statements
23 students made when discussing their interactions with exhibits were broadly similar, with a
24 predominance of observational statements, whether presented with a photograph or a video as
25 a stimulus for recall. These general patterns were also found regardless of when the interview
26 was conducted (Table 4). That is, most statements were descriptions of aspects of the exhibit
27 itself, what students did with it or the phenomena that could be observed. However, some
28 students were able to speak more generally about properties, and could provide causal
29 explanations for some of the phenomena they observed, sometimes even utilising their
30 existing science understandings in doing so. What is of interest is that this overall pattern
31 seemed to hold regardless of stimulus type or of the timing of the interview. Why might this
32 be? Is it possible that 3 months, even with an intervening summer holiday, was simply not
33 long enough for differences to appear? Or is it a fact that the dynamic nature of the video
34 makes little difference as a stimulus to recall when one is able to recall the whole episode and
35 mentally replay it in the mind? If so, it would suggest that the impact of the visit had been
36 significant, creating a memory that was sustained even several months after the visit – and a
37 memory which only required a small prompt to bring it to the fore again.

1
2
3 Although the general patterns of statements reflecting the cognitive dimension of the
4 visit were similar across stimulus type and interview timing, students seemed to refer to their
5 conversations with other students more often when looking at a video rather than a photo.
6
7 This could be because the element that videos do capture is the dynamic interaction between
8 students and the exhibit where conversation is often central. Hence the video may stimulate
9 recall of conversation which a still photograph may fail to do. However, it should be noted
10 that the sound was not of particularly high quality and students' comments did not always
11 directly refer to talk heard in the recording.
12
13
14
15
16
17
18
19
20
21

22 *Differences Among Exhibits?* The distribution of the types of statements was also
23 generally consistent across the various types of exhibits in this study. Table 6 reflects that in
24 discussing any exhibit students tended to describe the phenomena that they observed. They
25 provided more generalised comments and causal explanations less frequently, but such
26 statements – as well as those in which existing science knowledge was brought to bear – were
27 made in reference to all six exhibits used in this research.
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42

43 --- Insert Table 6 about here ---
44
45
46
47
48
49
50
51
52
53
54

55 One difference worth mentioning is that, when discussing the Bubble Race exhibit,
56 there were fewer instances of students bringing science concepts to bear, but they often
57 referred to the science process skill of fair testing. The nature of the exhibit – with a clear
58 comparison to be made and an intuitive way to repeat the test or comparison – seems likely to
59 have contributed to this difference.
60

The only other difference found in the data is that a smaller proportion of students' cognitive statements for Orbits were causal explanations, compared with cognitive statements they were making about the other exhibits. That the exhibit failed to stimulate causal

1
2
3 explanation may also be why students frequently described Orbits as 'just a game'. This
4
5 would suggest that it is erroneous to think that exhibits can speak for themselves with minimal
6
7 or no interpretation. Indeed many science centre exhibits are accompanied by either no or
8
9 very limited explanatory text. In addition, centres are often not able to provide sufficient staff
10
11 to facilitate interactions with exhibits. Visitors are often simply left to construct, for
12
13 themselves, an explanation. The result is an emphasis on the phenomenon as opposed to the
14
15 explanatory theory it illustrates. Yet it is theories of science that are the 'crowning glory of
16
17 science' (Harré, 1984). While it can be debated as to whether increasing visitors'
18
19 understanding of canonical theoretical explanations of phenomena is an appropriate or
20
21 reasonable goal for science centre visits, the data from this research reinforce that the goal of
22
23 supporting any development of science concepts is unlikely to be achieved without
24
25 scaffolding, either during or after the visit.
26
27
28
29

30 31 *The Visit as an Affective Experience*

32
33
34 While the findings described above suggest that the visit was memorable and offered
35
36 potential as a building block on which further understanding could be scaffolded, the trips
37
38 were also positive, enjoyable experiences for the students. When asked to rate how interesting
39
40 they had found the visit, 83% (107 students) ranked it as 'very interesting' and 15% (20
41
42 students) as 'interesting'. (The remaining two students claimed it was 'neither interesting nor
43
44 boring'). Similar patterns were seen whether students were interviewed shortly after the visit
45
46 or later, although a greater proportion of students considered it to be 'very interesting'
47
48 immediately after the visit (90%) compared with those who were interviewed 10-12 weeks
49
50 later (76%). Although the reason for this difference is unclear, it may be that after more time
51
52 had elapsed, the memory had faded somewhat and muted the students' recollection of how
53
54 interesting the trip had been.
55
56
57
58
59
60

1
2
3 Students were also asked to justify their ratings, and gave a variety of reasons. Some
4
5 students found their visit to be interesting because it offered multiple opportunities for
6
7 exploration and interaction with exhibits. According to one, 'I never knew you could do so
8
9 much stuff there, and do experiments and stuff' (*Leaf School*). Others considered it to have
10
11 been very interesting because they felt they had learned something. For instance, one student
12
13 claimed, 'You learnt loads of things on the different exhibitions' (*Chestnut School*).
14
15

16
17 Some students went further, describing the experience as something that had
18
19 combined both fun and learning. For example, 'It was interesting because you're having fun
20
21 and still learning science at the same time. So I quite liked it' (*Leaf School*).
22
23

24
25 Students also frequently contrasted their experience of the visit with school,
26
27 particularly their experience of science in school.
28
29

30
31 S1: Cos we went to Technquest it's kind of changed the way we think about
32
33 science.
34

35
36 S2: So then, so next time we do about air, we're going to think 'Oh I remember
37
38 from Technquest we did that.'
39

40
41 S1: But then it will seem boring because we'll have memories of Technquest
42
43 being really fun, and then you go into the lesson and you're like, 'Oh this
44
45 is really boring.' (*Sugaroak School*)
46
47

48
49
50 It makes science fun and that doesn't usually happen a lot. Because at
51
52 school everybody thinks science is boring, but it's not there. (*Redwood*
53
54
55
56
57
58
59
60
School)

In addition to providing reasons why they had found the visit to be interesting,
students were also asked to select which exhibit they had found to be most fun and which had

1
2
3 been most interesting for them and why. Although no one exhibit was chosen consistently, the
4
5 reasons students gave for choosing the exhibits they had were quite consistent. Students
6
7 frequently found exhibits to be fun or interesting because they allowed hands-on interaction.
8
9
10 As one put it, 'They're all interesting 'cos you pull on one and then the other one you like
11
12 chuck it in the air and it floats. That one you've got to spin it around' (*Sugaroak School,*
13
14 *about Heave Ho, Bernoulli Blower and Kugel, respectively*). Similarly, another said, 'We
15
16 were, like, turning the handle...' (*Maple School, Hydrogen Rocket*).

17
18
19
20 Students also spoke positively of exhibits which offered multiple opportunities for
21
22 exploration or interaction. For instance, the Kugel was liked because 'you have loads of
23
24 different ways and then you just spin it in loads of ways' (*Sugaroak School*)

25
26
27 What this suggests is that the opportunity to manipulate the material world remains a
28
29 key point of engagement for individuals – particularly in a society where such opportunities
30
31 are diminishing (Greenfield, 2009; Tapscott, 2009). When manipulating an exhibit, students
32
33 have an identifiable goal of comprehending how it works and possibly, as well, the
34
35 explanatory rules that govern its behaviour. Thus the exhibit poses a challenge permitting the
36
37 visitor to become engaged. In addition, interactive exhibits offer a sense of control –
38
39 something which the normal formal educational experience rarely affords (Paris, 1998).
40
41
42

43
44 Not surprisingly then, exhibits which did not seem interactive or controllable to
45
46 students were perceived as less fun or interesting. One student remarked, 'That one, you can't
47
48 touch the water inside' (*Maple School, Hydrogen Rocket*). Likewise, those that offered only
49
50 limited possibilities for exploration were viewed negatively: 'The rocket one, all you do is
51
52 turn the handle' (*Maple School, Hydrogen Rocket*).

53
54
55 However, a feature of exhibits that did engage many of the students was that they
56
57 offered an opportunity to collaborate with others. A different student praised the same exhibit
58
59 by saying, 'You had to help each other and everything' (*Redwood School, Hydrogen Rocket*).
60

1
2
3 In addition, the novelty of exhibits would also seem to contribute to engagement as
4 students were intrigued by, or enjoyed, exhibits that were novel or contrasted with their
5 previous experiences. In the words of one student, 'But with the blower one I found really
6 interesting because I've never seen something like that' (*Leaf School, Bernoulli Blower*).
7
8
9

10
11 Although novelty can detract from learning (Anderson & Lucas, 1997; Falk & Balling, 1982;
12 Falk, Martin, & Balling, 1978), statements such as the previous suggest that novelty can also
13 make experiences memorable.
14
15
16
17

18
19 Many students recounted the phenomenon that could be observed at an exhibit as
20 justification for selecting it as fun or interesting, implying that the phenomenon itself was
21 somehow of intrinsic interest (for reasons not entirely clear), while some students would go
22 further to explain that its value lay in the fact that they had found out or learned something: 'It
23 was very fun finding out that it [the bubble] would move faster through the oil' (*Leaf School,*
24 *Bubble Race*). Some students also stated that they appreciated exhibits which were perceived
25 as cognitively challenging: 'It's like a puzzle, which was quite hard' (*Sugaroak School,*
26 *Kugel*). Thus, these data suggest that some, and possibly all, students would value a visit
27 which, whilst permitting 'hands-on' manipulation, would also offer them the opportunity to
28 learn.

37
38
39
40
41
42

43
44 Notably, however, students' perceptions of which exhibits were most fun or
45 interesting varied and no distinctive pattern of engagement emerged. That is, one student may
46 have preferred a particular exhibit because it offered an opportunity to learn, while another
47 might have found it fun because it offered multiple opportunities for exploration. And yet
48 another student may have disliked the same exhibit because she found it offered a limited
49 repertoire of activities. Centres which offer a wider diversity of exhibits and potential
50 activities are, therefore, more likely to engage a wider set of young students.

Discussion

Looking across types of stimuli (photos and video), interview timing (shortly after the science centre visit or weeks later) and exhibit types, the interview data suggest that their visits provided highly memorable experiences for students. The way they interpreted or described the stimuli frequently went beyond what was observable in the photo or video. Students' statements ranged from fairly elaborate descriptions of the observable phenomena at the exhibits, to more generalised and even causal explanations of these phenomena or the science that students believed underlay the phenomena. Moreover, the data also demonstrate that these interactions with exhibits were positive, enjoyable, often social experiences for the students, and experiences from which they expected to learn.

Indeed, such an expectation may partially account for why students attempted to use their understandings of science to explain the exhibits. For, if they believed the trip to the science centre had to do with 'learning science', it is perhaps not surprising that students concluded that the exhibits themselves were meant to demonstrate something about science, and consequently, attempted to apply their understanding of science in interpreting their observations. Such expectations also reinforce recommendations made by researchers (e.g., Griffin & Symington, 1997) that teachers should emphasise to students that a visit to a science centre does have to do with learning science and that they should expect exhibits to demonstrate science concepts and principles.

That students participating in this research also found the experience of visiting a science centre to be enjoyable means that such visits provide an opportunity which can be exploited by teachers for student learning. Put differently, that a visit is so memorable, engaging, enjoyable and considered to be connected to science highlights the opportunities afforded by 're-visiting' the experience to build students' science knowledge. However, although students often tried to bring their science understandings to bear in interpreting the

exhibits, they were often incorrect, confused or inappropriate. Hence, such opportunities will only really be exploited by providing an occasion after the visit to reflect and re-engage with the phenomenon when their understanding can be developed and scaffolded.

For instance, the following conversation occurred between two students (and the interviewer) while looking at a photograph of themselves at the Heave Ho exhibit:

I: So, what can you tell me about that one and what you were doing with it?

S1: They're all the same. It's weird cos I think they're all the same kilograms, but they all feel heavier.

I: Mmm. So they feel...

S2: They're different.

I: Yeah. They feel different.

S1: Maybe it's because, like, you've tried one which is the lightest, then you go on to another and pull it again and lift your arms.

S2: Well, it might be something to do with the actual thing

S1: The rope's heavier.

S2: There are those things that you can pull engines up easy.

S1: Yeah, and the rope might have been heavier to pull and, like

S2: It might've been a longer rope and it might have been a bit more heavier. (*Sugaroak School*)

In the above excerpt it is apparent that the students noticed that the sensation of lifting the sacks suggested that they contained different weights, although they were labelled with the same weight. They offer two explanations of what they have observed – one concerning muscle fatigue and the other the weight of the rope. The second student also notices the

1
2
3 pulleys ('these things that you can pull engines up easy'). Unless student thinking is then
4
5 challenged, it is unlikely that their scientific understanding will be developed further. In this
6
7 case, the salient feature is that the ease of lifting is correlated with the number of pulleys.
8
9
10 Once this factor has been identified as the significant observation, the issue becomes one of
11
12 how the numbers of pulleys account for the observed difference in heaviness among the sacks.
13
14

15 Conclusions and Implications

16
17 In summary, the data from this exploratory study suggest that students were
18
19 cognitively and affectively engaged by the process of reflecting on their interactions with
20
21 science centre visits. From a cognitive standpoint, most of the students' statements were
22
23 descriptive. However, their comments did extend to attempts to provide causal explanations
24
25 and to use their science understandings to explain the phenomena they observed. In the
26
27 interviews students also reflected on the affective dimension of their visit, discussing what
28
29 made particular exhibits – and the visit as a whole – fun and interesting. Perhaps not
30
31 surprisingly, such factors included students' perceptions that exhibits were interactive or
32
33 hands-on, were novel, offered multiple opportunities for exploration, allowed collaboration
34
35 and combined fun and learning.
36
37
38
39

40
41 It is important to recall that these reflections on the visit did not occur in a vacuum.
42
43 They were stimulated by the photos and video clips and were elicited by interviewer
44
45 questions. Thus, the findings would seem to highlight the role of mediation in encouraging
46
47 these kinds of reflections which may, in turn, help students get the most out of their
48
49 interactions with exhibits as it is such mediation that may help scaffold students' developing
50
51 understandings of science concepts.
52
53

54
55 It can be challenging to provide such mediation during a science centre visit.
56
57 Anecdotally, the visits which formed part of the current research were not unlike what Paris
58
59 (1998) describes:
60

1
2
3 Most of them raced from one exhibit to the next, spending less time than a minute at
4
5 most and less than 20 seconds at many. They turned handles, pushed buttons, pulled
6
7 ropes, and sped to the next exhibit. Their motivation displayed free choice but their
8
9 behavior seemed directed at 'making things happen' or, at best, understanding *how* to
10
11 make each exhibit work rather than *why* it operated as it did. Some may call this a
12
13 performance goal; others may call it a procedural, as opposed to conceptual orientation
14
15 to exhibits. Still others might say it is an expected response pattern when you turn loose
16
17 a class of students with limited time to see many interesting exhibits. Regardless of the
18
19 reason, all three factors diverted children's motivation from understanding, and
20
21 exploring, and learning about the exhibits (p.23).
22
23
24
25
26

27 Such behaviour is likely to be attributable, at least in part, to the novelty of the setting.
28
29 A challenge for science centres is to balance the varying impacts of novelty. While science
30
31 centres often want to maximise the (cognitive) learning potential of visits, this is unlikely to
32
33 occur if students fail to go beyond the experience of simply sampling one exhibit after
34
35 another. Many centres also want to support the affective engagement elicited by the novelty of
36
37 the experience. Mediation, we would contend, is essential to achieving this balance. Whilst
38
39 students need to experience the excitement of freely exploring novel exhibits, they also need
40
41 help to identify the salient features of those exhibits. Undoubtedly, mediation can occur
42
43 during the visit and some students' statements reflected this possibility:
44
45
46
47
48
49
50

51 When you have people with you, you can talk about what weights are
52
53 which. And when you just go on your own, you just pick it up and drop it,
54
55 then pick it up and drop it and then there's no one to say 'What did you
56
57 find out about it?' (*Sugaroak School, Heave Ho*)
58
59
60

1
2
3 She [the teacher] was asking the question of which one would be travelling
4
5 the fastest and she was saying that, well, the motor oil was, cos it's a lot
6
7 thicker liquid, that the bubble would travel slower. (*Leaf School, Bubble*
8
9 *Race*)
10
11

12
13 Without the direction given by the teacher in the statement above, students may easily
14
15 miss the important scientific and technological aspects illustrated by the exhibit. Nevertheless,
16
17 an important implication of this study is that such mediation can *also* occur away from the
18
19 exhibit itself, when viewing video recorded at the exhibit. That this should be the case is not
20
21 surprising, given previous research which used video recordings to stimulate visitors'
22
23 reflection in informal learning environments (Stevens & Hall, 1997; Stevens & Martell,
24
25 2003). This study is significant, however, in showing the kinds of reflection that can be
26
27 prompted by such stimuli away from the science centre, even months after the visit.
28
29

30
31 Photographs and video thus offer a means by which can students can engage with both the
32
33 content and processes underlying exhibits in a way that could support or scaffold the further
34
35 development of science concepts, particularly when mediated by a teacher. Moreover, in
36
37 discussing video clips and photos, students may make their interpretations and understandings
38
39 more explicit – and as such, these reflections can in turn be used as a tool to construct
40
41 meaning from their experience.
42
43
44
45

46
47 To extend the learning potential of the visit, science centres could even make clips of
48
49 exhibit interactions available on their web sites. Alternatively, modern mobile phones permit
50
51 students to readily collect short clips of phenomena or exhibits they consider significant, and
52
53 many clips are publically available on YouTube. Informal conversations with teachers whose
54
55 classes participated in the current study indicated that such clips (even of other individuals)
56
57 would be a welcome and useful classroom resource to use either as an advance organiser to
58
59 help point out key features to observe or as a prompt to further discussion after the visit. The
60

1
2
3 data from the interviews conducted for this study indicate the kind of discussion that such
4
5 stimuli can generate. Moreover, photographs or video will enable students to re-visit a
6
7 positive experience, as well as supporting the kind of engagement and reflection useful in
8
9 building further science concepts. Such actions could, in turn, help maximise the potential of
10
11 science centre visits for learning. If the boundary between learning in formal and informal
12
13 contexts is to be dissolved, it is essential for museum educators and teachers to make use of
14
15 such media which will enable the value of the experience offered by the science centres and
16
17 experiences outside the classroom to be exploited as an educational resource for learning
18
19 inside the classroom. The findings of this study have, we hope, suggested one step to
20
21 achieving this goal.

Appendix 1: Exhibits

1
2
3
4
5
6
7 **Bernoulli Blower:** A stream of air is blown at an upwards angle out of a pyramid-shaped
8
9 base. The air flows over the top of a beach ball, creating lift and causing the beach ball to float
10
11 or hover in mid-air. (The ball must initially be held in the air stream and then released, in
12
13 order for the effect to be seen.)
14

15
16 **Bubble Race:** A wheel approximately three feet in diameter contains five tubes, each with a
17
18 different-coloured liquid. The wheel is mounted against a wall and can be rotated or spun.
19
20 When spun, air bubbles travel through the liquid from the bottom to the top of the tubes, with
21
22 their speed dependent on the viscosity of the liquid (water, motor oil, bubble bath, etc).
23
24

25
26 **Heave Ho:** Three sacks of identical weight (6 kg) are suspended with rope from a metal
27
28 frame, but each rope is held by varying numbers of pulleys (one, two, or three) at the top. The
29
30 sacks are opaque, and each has '6 kg' printed on one side. Depending on the number of
31
32 pulleys, each sack is easier or more difficult to lift, when the rope is pulled. The exhibit is
33
34 intended to demonstrate the mechanical advantage afforded by varying numbers of pulleys.
35
36

37
38 **Hydrogen Rocket:** Visitors spin a handle, causing gases to mix inside of a clear container.
39
40 Consequently, a small explosion (produced by the gases and accompanied by a 'pop') powers
41
42 a cork up a line, after which it falls back to its starting point.
43
44

45
46 **Kugel:** A large granite ball, weighing one half ton, is covered in water, which enables it to be
47
48 rotated (when pushed) on a cement base.

49
50 **Orbits:** Four golf ball-size balls can be spun or thrown across a surface. The exhibit itself has
51
52 an oval shape, but the surface slopes towards two holes. The shape of the surface causes each
53
54 ball to travel in a figure-8 shape, until eventually it spins around a single hole and drops in.
55
56
57
58
59
60

Footnotes

¹In this paper the term ‘exhibit’ is used to refer to a single interactive.

²A much shorter description of this work based on a few initial analyses of a subset of the data and some of the insights emerging have previously appeared in DeWitt (2008)

For Peer Review Only

Recollections of exhibits 1

Table 1

Information about classes and visits

School	Year group	No. students	Visit theme	Target exhibits	Interview timing
Leaf	Year 6 (age 10-11)	41 (19 interviews)	Investigate	Bernoulli Blower	Following week
				Heave Ho	
				Bubble Race	
Redwood	Year 6	17 (8 interviews)	Living in Space	Orbits	Following week
				Hydrogen Rocket	
Chestnut	Year 5 (age 9-10)	25 (13 interviews)	Living in Space	Orbits	10-12 weeks later
				Hydrogen Rocket	
Maple*	Year 5	6 (3 interviews)	Living in Space	Orbits	10-12 weeks later
				Hydrogen Rocket	
Sugaroak	Year 5	40 (20 interviews)	Forces	Bernoulli Blower	10-12 weeks later
				Heave Ho	
				Kugel

For Peer Review Only

Table 2

Types of student statements (all interviews)

Code	Frequency of use
Exhibit appearance	17% (390 statements)
Student action	18% (418)
Observed phenomenon	31% (720)
Fact	5% (116)
Exhibit-focused fact	7% (157)
Causal	12% (275)
Science skill	3% (79)
Science conception	7% (163)

Table 3

Types of statements made by stimulus type

Code	Video clip	Still photograph
Exhibit appearance	16% (176)	15% (121 statements)
Student action	18% (202)	20% (163)
Observed phenomenon	30% (326)	30% (240)
Fact	4% (40)	5% (38)
Exhibit-focused fact	7% (79)	7% (57)
Causal	13% (133)	13% (104)
Science skill	4% (47)	3% (25)
Science conception	8% (82)	7% (58)

N.B., The number of statements represented in this table is smaller than in Table 4. This is because Tables 2 and 4 reflect all of students' statements receiving a cognitive code, including those not made in response to any stimulus (photo or video).

Table 4

Types of statements by timing of interview

Code	Shortly after visit	Delayed
Exhibit appearance	13% (102)	19% (288)
Student action	16% (127)	19% (291)
Observed phenomenon	29% (228)	32% (492)
Fact	8% (63)	4% (53)
Exhibit-focused fact	6% (44)	7% (113)
Causal	14% (105)	12% (170)
Science skill	5% (38)	3% (41)
Science conception	10% (77)	6% (86)

Table 5

Interviews in which types of statements appeared at least once

Code	Interviews
Exhibit appearance	95% (60 of 63 interviews)
Student action	100% (63)
Observed phenomenon	100% (63)
Fact	68% (43)
Exhibit-focused fact	76% (48)
Fact AND/OR exhibit-focused fact	90% (57)
Causal	94% (59)
Science skill	54% (34)
Science conception	83% (52)

Table 6

Types of statements by exhibit type

Code	Bernoulli Blower	Bubble Race	Heave Ho	Kugel	Orbits	Hydrogen Rocket
Exhibit appearance	8%	11%	21%	18%	13%	20%
Student action	15%	16%	18%	20%	22%	20%
Observed phenomenon	33%	22%	24%	31%	38%	28%
Fact	6%	13%	6%	3%	3%	2%
Exhibit-focused fact	7%	15%	5%	8%	7%	7%
Causal	17%	13%	12%	12%	8%	13%
Science skill	4%	8%	6%	1%	2%	3%
Science conception	10%	2%	8%	7%	8%	8%
Total number of statements	426	134	342	302	320	486
